(Hourly observations.)

NOTE.—Station No. 1, Summit of Mount Washington. Elevation of barometer above sea-level, 6 285.4 feet; Station No. 2, Above Jacob's Ladder. Elevation of barometer above sea-level, 5,553.3 feet; Station No. 3, Waumbeck House. Elevation of barometer above sea level, 4,058.7; Station No. 4, Base of Mount Washington. Elevation of barometer above sea-level, 2,838.3. The elevation of barometers above sea-level at Stations Nos. 2, 3, and 4 were calculated from the synchronous barometrical observation taken during the month of June, 1873. Barometer-readings corrected for temperature and instrumental error only.

PAPER 16.

REPORT OF METEOROLOGICAL OBSERVATIONS MADE AT MOUNT MITCHELL DURING THE MONTHS OF MAY, JUNE, JULY, AUGUST, AND PART OF SEPTEMBER, 1873.

WAR DEPARTMENT,
OFFICE OF THE CHIEF SIGNAL-OFFICER,
DIVISION OF TELEGRAMS AND REPORTS FOR THE
BENEFIT OF COMMERCE AND AGRICULTURE,
Washington, D. C., September 23, 1873.

SIR: I have the honor to submit the following report of the special observations made on the summit of Mount Mitchell from May 11, 1873, to August 6, 1873, and both summit and base from the latter date to September 6, 1873. The barometers at both stations were carefully compared before leaving the office and also upon their return. Papers A and B, herewith, give in detail the instructions to the observers. Papers C, D, E, and F, are the journals kept at the summit, and Paper G that at the base-station. Papers H and I give the observations made at both stations, and, for purposes of comparison, those made at Knoxville, Tenn., during the same period. Knoxville was selected from the fact that its elevation is supposed to be accurately determined. The barometrical observations have been corrected for temperature and instrumental error only. The elevation of the barometer at summit above sea-level is assumed to be 6,691 feet; at base, 2,560 feet; at Knoxville, 993 feet.

Very respectfully, &c.,

H. W. HOWGATE,
Second Lieut. and Bvt. Capt. U. S. A., A. S. O. and Assistant.

CHIEF SIGNAL-OFFICER, U. S. A.,
Washington, D. C.

A.

WAR DEPARTMENT,
OFFICE OF THE CHIEF SIGNAL-OFFICER,
DIVISION OF TELEGRAMS AND REPORTS FOR THE
BENEFIT OF COMMERCE AND AGRICULTURE,
Washington, D C., April 26, 1873.

SERGEANT: Upon arriving at the summit of Mount Mitchell, in compliance with Special Orders No. 55, of this date, you will make suitable preparations for beginning a series of observations at 6 o'clock a. m. of May 1, and continuing them, without interruption, until midnight of May 31, at the following hours daily: 1 a. m., 2 a. m., 3 a. m., 4 a. m., 5 a. m., 6 a. m., 7.14 a. m., 8 a. m., 9 a. m., 10 a. m., 11 a. m., 12 m., 1 p. m., 2 p. m., 3 p. m., 4.14 p. m., 5 p. m., 6 p. m., 7 p. m., 8 p. m., 9 p. m., 10.39 p. m., and 12 midnight.

In making these observations local time will be used, which is twenty-one (21) minutes slower than Washington time. The observations will be the same in all respects as those made at regular stations, and will be recorded in the usual manner, upon Forms 4, omitting only the reduction of the barometric observations for elevation. The records of the party will be kept, under your supervision, by Sergeant Dietz, and will be brought by you in person to this office when ordered in, unless otherwise instructed in the mean time as to their disposition. The several instruments will be properly exposed, using the portable shelter as far as practicable, and read in the following order:

1. Attached thermometer.
2. Barometer.
3. Thermometer.
4. Hygrometer.
5. Wind-vane.
6. Anemometer.
7. Rain-gauge.

All observations will be entered as made in the "Original Record" book. In addition to a full supply of necessary forms, books of record, and articles of stationery, the following instruments will be furnished you:

2 barometers, mercurial.
2 standard thermometers.
2 hygrometers.
2 anemometers.

Digitized by Google

2 wind-vanes, small.
1 rain-gauge.
1 self-registering anemometer attachment, with battery and insulated wire.

Especial pains will be taken to secure a continuous record from the self-registering apparatus, and to preserve the record in proper condition for future use. All instruments and supplies will be taken charge of by you at this office. The former will be carried by yourself and the members of your party, and the latter must accompany you so as to reach the railroad-station nearest the mountain at the same time with the party. Upon arriving at Old Fort, the present terminus of the railroad, you will at once secure the necessary means of transportation for your party and supplies to the summit of the mountain, about thirteen miles distant. You will also ascertain from Col. D. C. Salsbury whether provisions in sufficient quantity can be obtained at or near the base of the mountain, and if not, will purchase and take with you enough to last the party five weeks. Water in abundance will be found within a few feet of the summit, and an old log-cabin on the summit can be used for shelter for the whole party. You have been selected to lead this party on account of your experience as an observer and thorough knowledge of station-duties, and it is expected that you will use your best efforts to make the expedition a successful one by the accuracy of the observations and the neatness of the records.

The utmost expedition must necessarily be used in order to reach the ground and get ready for work at the date and time ordered, and it is possible that you may be compelled to leave one man behind at the railroad-station to bring up the supplies, while the remainder of the party pushes forward to the mountain with the instruments to begin the observations.

In expending such public money as may be intrusted you for public expenses, the utmost economy must be exercised, and a carefully itemized account kept of all such expenditures.

Very respectfully,

H. W. HOWGATE,
Second Lieut. and Bvt. Capt. U. S. A., A. S. O. and Asst.

Sergt. WILLIAM E. SMITH,
Washington, D. C.

B.

WAR DEPARTMENT,
OFFICE OF THE CHIEF SIGNAL-OFFICER,
DIVISION OF TELEGRAMS AND REPORTS FOR THE
BENEFIT OF COMMERCE AND AGRICULTURE,
Washington, D. C., *July* 26, 1873.

SERGEANT: On arriving at Mount Mitchell you will put yourself at once in communication with Sergeant Smith, in charge of the summit station, and, after a careful comparison of your barometers and time-pieces with those in use at that station, will note the difference in your journal, and then proceed to some point at or near the base of the mountain, from which the summit can be distinctly seen, and there establish a station, at which you will make observations daily at the following-named hours, (local time,) until further orders, viz: 1 a. m., 2 a. m., 3 a. m., 4 a. m., 5 a. m., 6 a. m., 7.14 a. m., 8 a. m., 9 a. m., 10 a. m., 11 a. m., 12 noon; 1 p. m., 2 p. m., 3 p. m., 4.14 p. m., 5 p. m., 6 p. m., 7 p. m., 8 p. m., 9 p. m., 10 p. m., 10.39 p. m., 12 midnight. To insure similarity in time you will twice each day (8 a. m. and 4 p. m.) compare your time with that at the summit, by signals, using for this purpose the flags furnished, and of which one set will be turned over to Sergeant Smith at the summit station. The time-keeper at the summit will be used as the standard, and yours made to correspond with it at all times. Your station at the base must be located at or as near the general level of the surrounding country as possible, and its elevation above the railroad-track ascertained, if practicable. It is not necessary that you should have your station immediately at the base of the mountain, if there is any other point from which the summit can be better seen and communicated with.

Very respectfully,

H. W. HOWGATE,
Second Lieut. and Bvt. Capt. U. S A., A. S. O. and Asst.

Sergt. D. H. SACKETT,
Washington, D. C.

C.

Abstract of daily journal kept on Mount Mitchell, North Carolina, during the month of May, 1873.

May 1, 1873.—Arrived at 1 a. m. at the Mountain House, which is about 4,600 feet above the level of the sea, under heavy rain, with brisk and high southeast to east winds. The guides refusing to proceed any farther under such weather, made a delay necessary. Rain continued without interruption until midnight, and wind increased to very high.

May 2.—Rainy in the early morning, with very dense fog and brisk southeast wind until 10 a. m. Wind veering to north and rain ceased, with falling temperature. Started for the peak at 1 p. m., sending ahead the guides to clear the path with axes. Arrived at Mitchell's Peak at 6.30 p. m. Toward 7 p. m. snow commenced to fall, which soon changed to sleet, with increasing wind blowing from southeast, and with very low temperature, coating the trees and rocks with a thick layer of ice.

May 3.—Commenced to build a temporary instrument-shelter, and finished it by 12 m., and began to make observations. Wind blowing brisk from the west, with low temperature and light snow. Wind veering to north at 2.25 p. m., and at 4.40 p. m. to northeast, sleeting and hailing until 6.30 p. m. Wind backing to west and northwest, with slightly increased temperature, but still being below the freezing-point. Dense fog until midnight.

May 4.—Still dense fog and fresh and brisk northwest wind, which calmed down to an absolute calm at 9 a. m. Light north and west until noon, when the fog disappeared and disclosed cirrus and cumulus clouds. A second calm at 4.14 p. m., wind veering to southeast and east. Fog throughout the remainder of the day.

May 5.—Very foggy and damp weather, with fresh east wind. The fog above this station disappeared at 7.28 a. m., disclosing cirrus and cumulus clouds, but the whole region below this station was still hidden from view by fog until 9 a. m., when a dense fog enveloped the peak; wind in the mean time veering to southwest, being light, and calming entirely. The fog nearly disappeared at 5.32, with wind backing to south and southeast. Sky covered with cumulus clouds, and after their disappearance, at 9.03, the weather was fair for a few hours, with only a light fog in the valley. A halo was visible from 9 p. m. to midnight. At midnight the weather was foggy again.

May 6.—Foggy in the earlier part of the day. Partly fair and clear at 3 a. m., and continued fair until 6 a. m., with fresh east wind. Dense fog until 9 a. m., when a light rain commenced and continued until noon, and afterward heavy rain with sleet and hail. Temperature falling and wind increasing to brisk and high. The roof of the instrument-shelter was blown down, breaking the wet-bulb of the hygrometer, and making an immediate removal of all instruments to a place of safety absolutely necessary, which place (an overhanging rock) made a reading of them impossible. The storm increased in violence, and heavy rain, mingled with snow and sleet, fell in streams, compelling the whole party to discontinue the work and descend into the valley, there being no place nearer which could afford shelter.

May 7.—Owing to the continuance of the storm an attempt to proceed to the mountain and resume work was impossible.

May 8.—The storm having broken, started up the mountain in the morning, arriving at 3 p. m.; found the rain-gauge overflowing, which indicated a fall of over 4 inches during 48 hours.

May 9.—Fair weather, but having no place to expose the instruments made no observations.

May 10.—A log-cabin being so far finished to put the instruments in their places by 6 p. m., commenced work at 7 a. m.

The instruments are placed on the north side of the building as follows:

Elevation of the cistern of the barometer, (No. 185,) 3 feet 10 inches above the ground.

Elevation of the bulb of the thermometer, (No. 145,) 4 feet 5 inches above the ground.

Elevation of the bulb of the hygrometer, (No. 181,) 4 feet 5 inches above the ground.

Elevation of the anemometer, (No. 42,) 13 feet 4 inches above the ground.

Elevation of the anemoscope, 13 feet above the ground.

Elevation of the rain-gauge, 2 feet 6 inches above the ground.

The ground being a solid bed of rocks, made it impossible to have the gauge at the same level with the ground. A thunder-storm, with heavy rain and hail, passed over this mountain at 6.30 p. m., advancing from southwest to northeast. Light rain with brisk west wind during the remainder of the day. Rain-fall ceased at 11.18 p. m.; total amount .61 inch. Dense fog at midnight.

May 11.—A dense fog, with fresh and brisk west and northwest wind, prevailed until a few minutes after 10 a. m., when the weather became partly cloudy and fair, but with still fresh and brisk northwest wind. A halo from 7.30 p. m. until 11.18 p. m. Temperature declining slowly but steadily.

Digitized by Google

May 12.—Cloudy in the early morning, with light fog in the valley; wind continues brisk from the northwest. Dense fog from 4 a. m. until shortly after 6 a. m.; heavy frost. Fair weather and increasing temperature until 6 p. m. A distant and apparently very heavy thunder-storm west of this station, moving from northwest to southeast at 7.08. A heavy thunder-storm passed over this place, with heavy rain, from west to east, at 7.40, wind backing to west, and increasing to high. Fair weather, with light fog in the valley, from 8.32 p. m. until 10 p. m., when a light rain commenced to fall; clearing at midnight. Total amount of rain-fall during the day .45 inch. Halo from 8.45 until 10.16 p. m.

May 13.—Fair weather, with high and very high north and northwest winds, until noon; sky covered partly with cirrus clouds, the wind blowing steadily and variable from west and southwest, moderated until 8 p. m. to fresh with continuous fair weather. From shortly after 8 p. m. the force of the wind increased to high and brisk and backing to northwest. Weather cloudy.

May 14.—Partly cloudy and foggy in the morning, with brisk west wind. Light rain of but short duration at intervals during the entire day. Weather generally foggy and cloudy, and for a few hours only before midnight, fair. Wind very variable, backing to southwest, south, and southeast, and as far as due east. Total amount of rain-fall. .11 inch.

May 15.—Foggy weather with fresh southeast wind blowing steadily until 7.28 a. m., when it backed to east. Rain commenced to fall at 6.10 a. m. and continued until 4.45 p. m. The wind backed then to northwest and west and veering to north, being light and fresh but very variable. Dense fog prevailed throughout the remainder of the day. Total amount of rain-fall, .47 inch.

May 16.—Very foggy weather, with fresh variable north and northwest wind, until 7.33 a. m.; wind veering to northeast, backing again to northwest and west, and moderating to gentle during the forenoon. Generally fair weather, with light fog in the valley during the forenoon. At 9 a. m. well-defined cumulus clouds were visible far below this station. Cloudy weather with variable westerly and northerly winds during the afternoon and earlier part of the night. Fair weather, and for a short time perfectly clear weather, (at 10.39 p. m.,) until midnight.

May 17.—Fair weather, with brisk but variable northwest and west winds, in the early morning. Wind moderated to gentle and fresh during the day, and after backing in succession to southwest, south, and southeast, continued so until midnight. Fair weather with rising temperature continued until after 8 p. m. The lower atmosphere during the whole time very hazy. Cloudy until nearly midnight; fair at midnight.

May 18.—Foggy and cloudy weather, with fresh and brisk steady southeast wind, until 6.27 a. m., when the wind veered to the west and moderating in force. Cloudy weather during the forenoon and afternoon. Toward night the wind backed to south and southwest and increased to brisk. A light rain fell for a short time at 6.15 p. m. Foggy during the remainder of the day. Total amount of rain-fall, .01 inch.

May 19.—Foggy and cloudy weather, with brisk and high variable southwest wind, in the morning. The wind moderated in violence after veering to west, toward noon. Cloudy during the forenoon and afternoon, with wind backing to southwest and increasing to brisk. A distant thunder-storm passed east of this station at 1.15 p. m., moving from the southwest to the northeast. A light rain commenced to fall at 1.34 p. m., which was for 12 minutes accompanied by hail of considerable size, and continued until 2.32 p. m. Cloudy and threatening during the evening. Fair at midnight. Brilliant heat-lightning during the last three hours of the day, at first west and afterward north and northeast of this station, illuminating sometimes the entire heavens. Total amount of rain-fall, .30 inch.

May 20.—Fair weather, with high southwest wind in the earlier part of the day. Heat-lightning continued on the southwest horizon. Foggy, with fresh west winds, until 8.40 a. m. Fair and cloudy, with gentle but steady northwest wind, until noon. A phenomenon of peculiar nature occurred here during the latter part of the forenoon. The range of mountains of which Mount Mitchell is a part, divided the lower part of the atmosphere in two distinct halves. On the western side of this range the atmosphere was filled with haze, while the eastern side was foggy, and this fog was at times of considerable density. The line where fog and haze met was remarkably well defined and seemed to be unchangeable until shortly after 1 p. m., when a pretty dense fog filled the entire atmosphere. Foggy weather and light rain during the afternoon, with variable gentle and fresh easterly winds. A thunder-storm with heavy rain passed over this station at 4.20 p. m., moving from south to north. Cloudy and rainy weather, with brisk southeast wind, until midnight. Total amount of rain-fall, .56 inch.

May 21.—Foggy weather in the earlier morning, with brisk but variable southeast to east winds. Light rain commenced at 2.18 a. m., and ended at 6.45 a. m. Foggy until 9.52 a. m., when again it commenced to rain, ending at 10.24 a. m. Heavy rain from 12.20 p. m. until 1.25 p. m. Wind veering to southwest, and increasing to brisk, after being fresh and gentle, at 4.30 p. m. Dense fog filled the atmosphere, and a light, drizzling rain fell at 3.10 p. m., and continued until 9.28 p. m. Temperature rather

Digitized by Google

low for the season, and varying but little during the entire day. Cloudy and foggy until midnight. Total amount of rain-fall, .85 inch.

May 22.—Light rain at 12.23 a. m. until 1.45 a. m., with brisk variable southwest and west winds. Foggy weather until 5.40 a. m., when it commenced to rain, and continued until 7.01 a. m. A distant thunder-storm passed south of this station at 4 a. m., wind veering to west and northwest during the forenoon, moderating to gentle and fresh, with cloudy weather, which became fair during the afternoon. At 6.50 p. m. the wind veered to northeast, and weather continued fair. Toward midnight the weather was clear. Temperature rising slowly but steadily. Total amount of rain-fall, .21 inch.

May 23.—Fair weather with variable fresh and brisk westerly winds. From 5 a. m. until 8 a. m. foggy. Light rain commenced at 8.32 a. m., and ended 8.50 a. m. Fair weather with fresh and brisk north and northwest wind until midnight. During the latter part of the forenoon well-defined cumulus clouds were at a considerable distance below this station. Brilliant heat-lightning during the evening continued until midnight, first on the eastern and southern horizon, afterward on the southern and western horizon, and, finally, on the western horizon only. Temperature rising slowly throughout the day. Total amount of rain-fall, .05 inch.

May 24.—Foggy at the beginning of the day, with brisk westerly winds. Cloudy and fair weather with fresh west and northwest winds until 3.45 p. m., from which time the weather continued fair until midnight. The wind, after veering to north and northeast, and increasing to very brisk, and moderating only a few hours before midnight, very variable during the entire day. Heat-lightning of short duration at 9 p. m. on western horizon.

May 25.—Fair weather, with brisk and fresh northeast and east winds, until 10.40 a. m., when the whole sky was covered with heavy cumulus clouds. A thunder-storm with heavy rain and hail, the size of which was fully equal and for a few minutes exceeded that of the largest kind of buckshot during the time of its fall, (20 minutes,) passed over this station at 11.40 a. m., moving from southeast toward northwest. During its passage the wind had every possible direction, veering and backing to and from every point in the compass in rapid succession until at 12.40 p. m. the wind veered to east again, by which time the storm had passed. Cloudy weather with very variable but fresh and light northeast and southeast winds during the afternoon. Distant thunder-storms in southwest and east, the former moving from northwest to southeast, the latter from northeast to southwest at 4 p. m., and at 5 p. m. thunder-storms in southwest and west direction of this station. Fair weather from 9.10 p. m. until 11.25 p. m., when a dense fog filled the atmosphere. Temperature declining. Total amount of rain-fall, .47 inch.

May 26.—Foggy weather, with steady, fresh and brisk southeast wind in the early morning, until 7.25 a. m., when a heavy rain with fresh southwest wind commenced to fall, ending at 9.10 a. m. Cloudy and foggy weather with wind backing and veering from southwest to southeast until noon, when in short succession two thunder-storms passed this station, both moving from southwest to northeast. Cloudy and foggy weather until the close of the day with fresh and brisk southerly and easterly winds. During the afternoon a distant thunder-storm passed north, and shortly afterwards another southwest of this station, both moving in a direction from southeast toward northwest. Between the hours of 3 p. m. and 4.30 p. m., heavy and well-defined cumulus clouds were in the valleys east and southwest of this station, nearly 500 feet below the summit of Mount Mitchell. Temperature slightly rising. Total amount of rain-fall, .42 inch.

May 27.—Foggy weather, with variable and brisk southwest wind, until 4.30 a. m. Fair, with brisk westerly winds, which toward noon moderated to gentle, during the entire forenoon. During this time heavy cumulus clouds were filling the valleys below this station, varying from 200 to 500 feet below. A heavy thunder-storm advancing from the southwest to the northeast passed with heavy rain and very large hail (the latter continued to fall for five minutes) over this station. The wind's force increased after the passage of this storm from gentle to high, moderating only for a brief period at midnight to brisk. Weather cloudy in the evening and fair until midnight. Temperature slightly falling. Total amount of rain-fall, .52 inch.

May 28.—Clear weather, with very brisk southwest wind, until a few minutes after 2 a. m., when the sky became overcast with cumulus clouds. Light rain soon began to fall from 3.30 a. m. until 4.45 a. m. The wind, after veering to west, and shortly afterward to northwest, moderated to fresh. Fair weather until noon. Small cumulus clouds in the valleys below this station during the greater part of the morning and forenoon. Cloudy weather, which, for only two short hours, from 8.16 p. m. to 10 p. m., was cleared to fair, prevailed until midnight. Westerly and northwesterly winds, fresh and gentle, steady in the fore part of the afternoon, and variable until midnight. A light rain-shower passed over this station from 5.40 p. m. until 5.55 p. m; temperature slightly increasing. Total amount of rain-fall, .04 inch.

May 29.—Cloudy weather with fresh northwest wind at the beginning of the day.

Digitized by Google

At 1.55 a. m. light rain commenced to fall, and continued until 10.15 a. m. After the rain had changed from light to heavy, by 8 a. m., the wind, very variable, backed from northwest to southwest, veered to southeast, and backed again to west during the forenoon, and increased at 9 a. m. to brisk, but moderated at noon to fresh; cloudy weather, with very variable westerly winds, during the afternoon and evening. From 2.55 until 3.10 a light rain-fall. Heavy cumulus clouds in the valleys east and south of this station, whose upper limits sometimes on a level with this station, sometimes a trifle higher, and sometimes as much as 200 feet below this station. Foggy weather, with fresh but steady southwest wind, until shortly before midnight, when the fog disappeared and the weather became cloudy; temperature slightly falling. Total amount of rain-fall, 1.21 inch.

May 30.—Cloudy and foggy weather from beginning of the day until noon, with fresh and brisk westerly winds. A light rain fell from 2.25 a. m. until 2.40 a. m. Foggy and cloudy, with at first variable northerly winds, which, by 5 p. m., became a steady northeast wind until midnight. Heavy thunder-storms passed at noon north and west of this station, and in the earlier part of the afternoon northeast of this station. Heavy and afterward light rain from 3.20 p. m. until 5.20 p. m. At midnight the weather was fair; temperature falling. Total amount of rain-fall, .36 inch.

May 31.—Foggy weather, with fresh and brisk northeast wind, which, until shortly after 7 p. m., was steady and variable until midnight. Light rain from 6.40 a. m until 8.45 a. m. The dense fog which prevailed on this station throughout the entire day disappeared for only a few minutes at 1 p. m. Temperature very low for the season. Total amount of rain-fall, .17 inch.

MONTHLY SUMMARY.

Mean temperature from May 11 to May 31	49°.3
Rain-fall from May 10, 6 p. m., to May 31	6.81 in.
Number of rainy days from May 10, 6 p. m., to May 31	17
Prevailing winds from May 10, 6 p. m., to May 31	N. and W.
Number of miles traveled from May 10, 6 p. m., to May 31	6,508

The cabin is built immediately on the peak, which is a flat, rugged place, about 80 feet long and 40 wide. It stands exactly north and south; is 16 by 14 feet; has a window in each end, and the door is on the west side, the chimney on the east. The thermometer and hygrometer are in a shelter built over the north window. The barometer hangs on the east side of the window, next to which stands the self-registering attachment to the anemometer. The anemometer is placed on the north end of the roof, and a few feet from it is placed the vane. The rain-gauge is placed on the ground to the southwest of the cabin some 40 feet, and has a full exposure. Instruments all in good condition.

Respectfully submitted.

W. E. SMITH,
Observer-Sergeant Signal-Service, U. S. A.

D.

Journal abstract from June 1 to June 30, 1873.

MOUNT MITCHELL, NORTH CAROLINA.

June 1, 1873.—Foggy weather, with variable brisk east wind at the beginning of the day. Fair weather, with steady northeast wind, which, until 6 p. m., was light and gentle, and afterward became brisk, until midnight. Cloudy, foggy, and fair weather until midnight. Temperature rising. Between 6 p. m. and 8 p. m. the thermometer fell considerably, but rose slowly until midnight.

June 2.—Fair and clear weather, with variable brisk east wind at the beginning of the day. From 4 a. m. the wind moderated to fresh, and continued so until shortly after 7 p. m., with partly fair and foggy weather and increasing temperature. Toward night the fog became more dense, and light only for a brief time, at 10 p. m, with wind increasing to brisk and veering to northeast, but backing toward midnight to southeast, by which time its force moderated to fresh. Light rain commenced to fall from 11.15 p. m., lasting until midnight. Total amount of rain-fall during the day, .04 inch.

June 3.—Light rain continued until 1.43 a. m. Foggy weather, with very variable easterly winds, which, until 3 p. m., were fresh, increasing to brisk until after 9 p. m., when they moderated to fresh again, throughout the day. Heavy rain commenced at 9.15 p. m., becoming light at 10.20 p. m., but heavy again until midnight. The wind

Digitized by Google

became, by 7 p. m., a steady east one, and continued so until the close of the day. Temperature falling. Total amount of rain-fall during the day, .53 inch.

June 4.—Rainy weather, with variable fresh and brisk south and southwest winds, continued until 5.10 a. m., the rain being partly heavy, partly light. Foggy and cloudy weather, with fresh southwest wind, which during this time was steady until noon, interrupted only for 25 minutes by light rain at 11.20 a. m. Foggy and cloudy weather, with variable fresh southerly and westerly winds, until 3.10 p. m., when a light rain fell until 4.30 p. m., during the afternoon. Fair weather from 6.40 p. m. to 8.25 p. m., with variable brisk westerly winds. Foggy until midnight. Heat-lightning on west and northwest horizon at 8 p. m. Temperature slightly increasing. Total amount of rain-fall during the day .60 inch.

June 5.—A very dense fog, with very brisk westerly winds and interrupted only once by a light rain-shower at 2.15 a. m., prevailed on this station until noon. Foggy and rainy weather until midnight. A very heavy rain, the heaviest experienced so far at this place, fell from 6.08 p. m. until 7.05 p. m., the depth of which amounted to .44 inch. Wind continued variable and brisk, westerly; temperature falling. Total amount of rain-fall during the day, .83 inch.

June 6.—Rainy weather continued, with brisk and fresh variable northwest and west winds, until 12.00 p. m.; foggy weather, with variable northwest and north wind, until midnight, by which time the wind's force had greatly moderated. A light rain-shower in the afternoon from 4.22 p. m. until 4.48 p. m.; temperature still falling. Total amount of rain-fall during the day, .48 inch.

June 7.—Fair weather, with fresh north wind, in the early morning. The wind being variable backed shortly after 2 a. m. to northwest. As soon as the wind backed, the atmosphere was filled with fog, at first somewhat pretty dense, afterward light, and lasted so until 5.20 a. m. when the weather became fair. Shortly before noon and for three hours in the afternoon the weather was cloudy, but continued fair from 3.10 p. m. until midnight. The variable north and northwest wind moderated in force greatly, being gentle from 10 p. m. and backing to south and southwest by midnight. Temperature slowly rising.

June 8.—Fair weather, with gentle but variable southeast wind, until 3.30 a. m., when the weather became clear and remained so for a little more than two hours. Generally fair until 9.20 a. m., with gentle and light southeast and east winds. By 9.20 a. m. the wind veered to south and toward noon to southwest and the sky became covered with heavy cumulus clouds moving from the west. The weather continued cloudy until 2.45. p. m., and then became foggy, remaining so until midnight. At 2.45 p. m. the wind backed suddenly to the east, increasing at the same time from fresh to brisk. The temperature which, until 2.45 p. m. was steadily but slowly increasing, fell rather rapidly until the close of the day. Light rain-shower from 8.10 p. m. to 8.40 p. m. A drizzling rain commenced at 11.25 p. m. and lasted until midnight. Total amount of rain-fall during the day, .05 inch.

June 9.—The light, drizzling rain continued until 1.41 a. m., the wind being variable, brisk east wind, moderated at 4.30 a. m. to fresh, and veered to south. Thermometer continued to fall until after 4 a. m. Weather foggy until after 5 p. m. The wind, after veering to southwest by 7 a. m. and to west at 9.45 a. m., became light. At 4 p. m. the wind veered to northwest and a calm ensued from a little before 7 p. m. until shortly after 8 p. m. Afterward a gentle northwest wind sprung up, backing shortly to west and southwest, and increasing to fresh by midnight. Cloudy weather from 5.25 p. m. until 11.40 p. m., when a pretty dense fog enveloped this peak. The temperature, which had been slowly rising during the day, fell again toward midnight. Total amount of rain-fall during the day .09 inch.

June 10.—Cloudy weather, with light and gentle variable and steady southwest wind and very slowly rising temperature, until noon. Light rain-showers from 8.05 a. m. until 8.40 a. m. and from 10.50 a. m. until 10.55 a. m. Cloudy weather, interrupted for a short time by a dense fog at 3 p. m. and fair weather from 4.40 p. m., until 7.10 p. m., prevailed throughout the remainder of the day. Light rain from 12.25 p. m. until 12.45 p. m. The wind increased shortly after noon to fresh and brisk, and after 9 p. m. to high, and remained so; a variable southwest wind until midnight. The temperature, which until 2 p. m. was rising, began to fall rapidly until 8 p. m., continuing steady, but low for the season, until the close of the day. Total amount of rain-fall during the day, .08 inch.

June 11.—The high variable southwest wind of the previous day continued until after 1 a. m., when it moderated to brisk and veered to west by 4.20 a. m. Cloudy weather, until after 3 a. m., interrupted, from 1.25 a. m. to 1.38 a. m., by light rain. Foggy from after 3 a.m. until 4.07 a. m., when a light rain commenced to fall, ending at 7.45 a.m. Foggy weather afterward, until 11.35 a. m., when again a light rain commenced; by this time the brisk west wind had backed to southwest, and moderated to fresh, remaining so until 6 p. m., but veering to west at 2.40 p. m., at the exact time the rain ceased, and, toward 5 p. m., to northwest, and backing shortly before 6 p. m. to southwest. Foggy weather, with brisk southwest and west wind until 7.35 p. m., when a

Digitized by Google

light drizzling rain commenced to fall, not ceasing at midnight. At midnight the wind had veered to west, and moderated to fresh. Temperature low for the season. Total amount of rain-fall during the day, .61 inch.

June 12.—The drizzling rain of the previous day ended at 12.40 a. m. The weather then became foggy, and continued so until noon, with the exception of a light rain from 4.05 a. m. until 4.25 a. m., and a very light fog at 11 a. m., disclosing the sky covered with cumulus clouds. The wind continued to be a very variable westerly wind, mostly fresh, until 9.45 a. m., when it veered to northeast, and, after blowing from this point for about two hours, veered suddenly to the south, but backed by 1 p. m. again to northeast; at 4.20 p. m. the wind veered to east, and continued a fresh variable east wind until midnight. During the afternoon the weather was at first cloudy, afterward foggy; and, by 4.18 p. m., rainy, and continued so until midnight. Temperature low and slightly falling toward night. Total amount of rain-fall during the day, .55 inch.

June 13.—The weather was, after the drizzling rain ended at 12.10 a. m., foggy until 3.25 a. m., when the somewhat dense fog disappeared, leaving a very light fog only, and disclosing the sky partly covered with cumulus clouds. By 7 a. m. the fog became denser, and, hiding everything from view, remained so until the close of the day, disclosing only once, at 6 p. m., during the entire time a great part of the sky. Toward midnight the fog was very dense. The wind, during the entire day, was very variable. The fresh northeast wind, after moderating in force, backed, at 4.15 a. m., to west, and, moderating to light, veered, at 7 a. m., again to northeast, but backed, by 8 a. m., to north; by 11 a.m., to northwest, and, before noon, to west, after which time it veered to northwest, and continued, until 5.40 p. m., when, after increasing to gentle, the wind backed to southwest, and, increasing still more to fresh, backed, shortly after 9 p. m., to east, remaining so until midnight. Temperature slightly increasing.

June 14.—Foggy weather, with fresh southeast wind, from the beginning of the day until 1.35 a. m., when the wind veered to southwest and a light rain began to fall, ending at 2.40 a. m., from which time the weather continued foggy until 11.15 a. m. The fog toward noon became very dense. The variable southwest wind increasing in the early morning to brisk, but moderating by 7 a. m. to fresh, backed soon to south, and shortly afterward to southeast. At 11.15 a. m. a heavy rain commenced and continued, partly heavy, partly light rain, until 6.15 p. m. At the same time the rain commenced to fall the wind backed to east, but veered to southeast and southwest in short succession, and backed again to east by 4.30 p. m. At ten minutes before 6 p. m. the wind veered to southwest, and at 9.15 p. m. to west, remaining so. A very variable fresh and gentle wind until midnight. After the rain ceased to fall the fog cleared for a short space of time, disclosing the sky, covered with cumulus clouds, and the valleys surrounding this peak filled with heavy cumulus clouds, whose upper limits were apparently from 500 to 800 feet below this station. Partly foggy and fair weather until midnight. Temperature slightly diminishing. Total amount of rain-fall during the day, .89 inch.

June 15.—Fair and foggy weather, with brisk and variable northwest wind, until noon, by which time the wind's force had moderated to fresh. At 1 p. m. the fog gradually disappeared, disclosing the sky, covered with heavy cumulus clouds. The weather became cloudy, and continued so until nearly 7 p. m., when it cleared to fair, and continued so until midnight. The variable fresh northwest wind became at the same time a steady northwest wind, and moderated to gentle by midnight. Temperature slightly increasing.

June 16.—Generally fair weather with variable fresh westerly winds, which at 3.40 a. m veered to northeast, but backed to northwest again, after moderating to gentle and light, at 10.25 a. m. At the same time the weather became cloudy, and continued so until midnight, only once, at 6 p. m., clearing to fair for a few minutes. The wind being mostly light and gentle was a variable westerly, when at 8 p. m. it became a steady west wind, and after veering at 10.30 p. m. to northwest, a steady northwest wind, remaining so until the close of the day. The temperature during the entire day was considerably rising.

June 17.—Cloudy weather continued until 5.20 a. m., when it became fair until 9.40 a. m., by which time the sky again was covered with cumulus clouds, continuing so until 4 p. m. At 4 p. m. the cumulus clouds greatly disappeared, leaving the weather fair, but for two hours only, when the sky was entirely clouded over. At 6.50 p. m. this peak was enveloped in fog, remaining so until midnight. The steady northwest wind veered by 4 a. m. to northeast, becoming variable, and after moderating from fresh to light, veered by 9 a. m. to south, by 11 a. m. to southwest, and at noon to northwest. Shortly after noon, after the wind had veered still farther to north, and backed again to northwest, its force increased to gentle, and backing to west increased to fresh. At 7 p. m. the wind had veered to northwest, but backed at 8.35 p. m. to southwest, and after increasing to brisk remained a variable brisk southwest until midnight. A distant thunder-storm passed at 12.10 p. m. southeast of this station, moving from southwest to northeast. Heat-lightning from 8 p. m. until 10 p. m. northeast of this station, and apparently very close by. Temperature rising.

Digitized by Google

June 18.—Foggy weather at the beginning of the day, which, after the fog had disappeared, nearly, at 1.20 a. m., became fair, and continued so until shortly after 3 a. m., when the weather became, for about 30 minutes, cloudy, and foggy afterwards. By 9.15 a. m. the fog disappeared, leaving the weather fair, but for a short time only, becoming at 2 p. m. cloudy and threatening. Light rain began to fall from 2.15 p. m. until 4.25 p. m., after which time the weather was generally foggy until midnight, with the exception of only a short time, at 6 p. m., when it was cloudy. Variable brisk and fresh westerly winds prevailed during the entire day. A heavy thunder-storm passed southwest of this station, moving from west to east, at 2 p. m. Temperature slightly falling. Total amount of rain-fall during the day, .14 inch.

June 19.—Foggy weather, with variable brisk northwest and west winds, until 10.40 a. m., when, after the weather was for not fully one hour fair, it became cloudy, and continued so until 2.15 p. m. At this time light rain began to fall, ending at 2.45 p. m. The wind had by this time moderated to fresh, and was a variable west wind. Foggy and rainy weather until midnight. The wind at 7.45 p. m. increased to brisk and high, being a variable northwest and west wind, and continued so until midnight. At 2 p. m. a heavy thunder-storm passed southwest of this station, moving from west to east. Temperature steady. Total amount of rain-fall during the day, .15 inch.

June 20.—Light rain and foggy, with brisk and high west winds, until 4.18 a. m., when the rain ended. Foggy weather, with variable brisk west wind, until 8.10 a. m., when the wind veered to northwest, but backed shortly afterward to west, and a heavy rain began to fall, ending at 1.15 p. m. The weather then became foggy and remained so until midnight, with the exception of the time from 3.15 p. m. to 3.50 p. m., when a light rain fell. The wind continued to be a variable west wind until 8.25 p. m., veering then to northwest, and, moderating slightly in force, remained so until midnight. Temperature nearly uniform throughout the entire day. Total amount of rain-fall during the day, 1.50 inch; the heaviest fall during twenty-four hours so far recorded.

June 21.—Foggy weather, with brisk variable northwest wind, prevailed until 6.25 a. m. The fog now disappeared, and the weather became fair, remaining so until 1.20 p. m., when the sky became overcast with cumulus clouds, which again cleared away at 6.45 p. m. Fair weather from 6.45 p. m. until midnight. At 8.15 a. m. the variable northwest wind veered to northeast and moderated to fresh, but backed by 10 a. m. to north, and having become a gentle wind, continued a variable northerly to westerly wind until 8.10 p. m., when, after increasing to fresh, the wind was a variable southwest wind, remaining so until midnight. Heat-lightning on southern horizon at 10 p. m. Temperature slightly rising.

June 22.—Fair weather, with fresh variable westerly winds, which by 7 a. m. moderated to light, prevailed until 9.40 a. m. followed by cloudy weather, which continued until 5.41 p. m., with the exception of the time from 2.30 p. m. to 2.55 p. m., during the passage of a thunder-storm moving from west to east, with heavy rain and a small amount of hail. Light rain began to fall at 5.41 p. m., ending at 7.14 p. m. The weather then became cloudy until 9.18 p. m., and partly fair and foggy until midnight. The light variable westerly wind veered at 12.10 p. m. to northeast, and at 2.30 p. m. to east, increasing in the mean time to gentle, and after backing to southwest at 3.25 p. m. and increasing to fresh, continued a variable southwest wind until midnight. From 2 p. m. until shortly after 4 p. m. this peak was completely surrounded by thunder-storms, of which only one passed over it, at 2.30 p. m. Heat-lightning southeast of this station at 8 p. m. Temperature steady. Total amount of rain-fall during the day, .29 inch.

June 23.—Foggy weather from the beginning of the day until 2.50 a. m., when for nearly one hour the weather became fair, and cloudy afterwards. At 5.48 a. m. the weather had cleared to fair, and continued so until after 9 a. m., when it became again cloudy and threatening at noon. A heavy rain fell from 12.04 p. m. until 12.21 p. m. Cloudy weather then prevailed until 5.35 p. m., when a thunder-storm, advancing from northeast to southwest, passed this station, with heavy and light rain from 5.35 p. m. to 7.14 p. m. Light rain again began to fall at 9 p. m., ending at 11.05 p. m., from which time until midnight the weather cleared to fair. Variable fresh westerly winds prevailed until 7 a. m., when they moderated to gentle, and to light at noon. At 2.30 p. m. the wind backed to east, and, after increasing to fresh, veered at 4 p. m. to southwest, at 4.30 p. m. to northwest, and at 9 p. m. to northeast, and, after moderating to gentle and light, continued so until midnight. Several thunder-storms passed by this station, one at 11 a. m. in the northwest, another at 1 p. m. in the east, moving from south to north. Two thunder-storms at the same time were seen, at 4.14 p. m., in the northwest and west. During the passage of the thunder-storm over this station the temperature fell very rapidly, but rose again slowly toward midnight. Heat-lightning in the northeast at 9 p. m., and in the south from 9 p. m. until midnight. Total amount of rain-fall during the day, .41 inch.

June 24.—The day began with fair weather until 5.40 a. m. Foggy, and shortly afterward cloudy, until 7.25 a. m. Fair weather then continued until noon. During the afternoon, until 6.15 p. m., the weather was cloudy and threatening; at 3 p. m.

Digitized by Google

two distant heavy thunder-storms passed by this station. One thunder-storm was in the south, moving from southwest to northeast; and the second, at the same time, in the northeast, moving from north to south. A third distant thunder-storm passed by at 3.25 p. m., moving from west to east. At 7 p. m. the weather had cleared to fair, and by 9 p. m. this peak was shrouded in fog, which continued until midnight. The wind was, during the entire day, very variable. A gentle northeast wind veered, at 1.15 a. m., to southwest, and, after increasing to fresh, continued a variable northwest and west wind until 9.10 a. m., which by 10 a. m. had veered to west, and by 11 a. m. to northeast. From after 11 a. m. until after 4 p. m. a light northerly wind prevailed, and, after increasing to fresh, continued a north to northwest wind until midnight. Temperature increasing slightly.

June 25.—Foggy and fair weather, with variable fresh and gentle northwest to northeast winds, prevailed until 10.40 a. m.; the weather became cloudy and threatening at 4.14 p. m. At 4.20 p. m. a heavy rain began to fall, moderating by 5 p. m. to light, and ending at 5.32 p. m. Light rain again began to fall at 6.40 p. m., with wind veering to east, and continued until midnight. Temperature high and rising until 2 p. m., but declined very rapidly toward night. Total amount of rain-fall during the day, .78 inch.

June 26.—Light rain ended at 12.38 a. m. Foggy weather afterward until 3.50 a. m., from which time cloudy weather continued until 8.10 a. m. Foggy weather then prevailed until 9.11 p. m., when a light drizzling rain commenced to fall, and continued until the close of the day. Fresh, steady, and variable east wind prevailed until after 7 a. m., moderating then to light, and backing shortly afterward to northwest. By 1 p. m. the wind veered to north, and at 1.25 p. m. to northeast. After increasing to fresh the wind veered, at 4 p. m., to east, and increasing to brisk shortly after 6 p. m., but moderating to fresh again after 8 p. m., veered, at 10.30 p. m., to southeast, and continued so until midnight. Temperature falling. Total amount of rain-fall during the day, .23 inch.

June 27.—The light drizzling rain of the previous day ended at 3.25 a. m. Cloudy weather afterward until 5.15 a. m. At 5.15 a. m. a thick fog surrounded this station, and remained so until midnight, only diminishing in density during the afternoon and night. The fresh southeast wind veered by 3 a. m. to south, and shortly after to southwest, and after becoming gentle during the forenoon and light from 1 p. m. until 4.14 p. m., remained, after increasing to fresh toward night, a partly steady, partly variable southwest wind until midnight. Temperature steady, but rather low. Total amount of rain-fall during the day, .13 inch.

June 28.—Foggy weather, with fresh variable southwest wind, which at 7.49 a. m. veered to west, prevailed until 1.25 p. m. The fog then suddenly disappeared, disclosing the sky covered entirely with heavy cumulus clouds, but shortly after 3 p. m. fog again surrounded this peak and continued the remainder of the day, the time from 6.20 p. m. to 8.17 p. m. excepted, during which a light rain fell. By 1 p. m. the wind had moderated to gentle, and had become a steady west wind, but after increasing to fresh at 5.45 p. m. was variable. After 10 p. m. the wind veered to northwest and, moderating to gentle, continued so until midnight. Temperature slowly rising. Total amount of rain-fall during the day, .15 inch.

June 29.—Foggy and rainy weather throughout the day, but rainy chiefly during the afternoon and evening. The wind until 2.50 p. m. was a variable, fresh, and gentle west to southwest wind. At 2.50 p. m. the wind backed to south, and shortly before 5 p. m. to southeast, remaining so until midnight. Temperature rising slowly. Total amount of rain-fall during the day, .59 inch.

June 30.—Foggy and rainy weather, with falling temperature, continued throughout the day, the rain being partly heavy, partly light rain. Variable fresh and brisk southeast to east winds prevailed until noon, when the wind veered to southwest, and shortly afterward to west. At 3.45 p. m. the wind again veered to northwest and remained fresh and brisk until midnight. Total amount of rain-fall during to-day, .95 inch.

MONTHLY SUMMARY.

Mean temperature during June, 1873	54°.1
Highest observed temperature	70°
Lowest observed temperature	41°
Total amount of rain-fall	10.07 in.
Number of rainy days	22
The prevailing winds were from	N. W. and W.
Number of miles traveled	8,029

Instruments in use are all in good condition.

Abstract of daily journal kept on the summit of Mount Mitchell, North Carolina, from July 1 to July 31, 1873.

July 1.—Foggy weather continued, with brisk, variable westerly wind, until 9.40 a. m., when the fog disappeared and fair weather ensued, remaining so until after 2 p. m.; cloudy from 3 p. m. until 6 p. m. By 7 p. m. the weather was fair again, and clear by 10 p. m., remaining clear until midnight. By 12 m. the brisk northwesterly wind had moderated to fresh, and backed after 5 p. m. to westerly, and by 8 p. m. to southwesterly, increasing to brisk in the mean time and remaining so until midnight. Temperature rising during the day, but falling toward night.

July 2.—Clear weather until 2.10 a. m., when fair weather followed, and continued until noon; cloudy until 4.30 p. m.; fair weather then prevailed the remainder of the day. Variable, brisk southwesterly wind prevailed until 6 a. m. The wind moderated to fresh after 6 a. m. and veered to west and northwest, and becoming gentle, backed at 2.20 p. m. to southwest, and continued, after increasing to fresh and to brisk at 11.45 p. m., until midnight. Three distant thunder-storms passed by the station, one at 2 p. m., northeast of the station, moving from east to west, another at 2.40 p. m. in the east, moving from northeast to southwest, and the third at 4.05 p. m. in the northwest, moving from south to north. Temperature rising throughout the day.

July 3.—Generally fair weather with steady, high temperature, and variable northwesterly to southwesterly winds, which in the earlier part of the day were brisk and fresh, but moderated to gentle and light at noon, and increased to fresh toward night, prevailed during the day.

July 4.—Fair and foggy weather, with fresh westerly winds, until noon. The wind calmed for a brief period at noon and the weather became cloudy; generally fair weather, with variable fresh and brisk westerly winds, until midnight. Heat-lightning from 10.10 p. m. until midnight. Temperature high and rising.

July 5.—Foggy at the beginning of the day. A heavy thunder-storm, with heavy rain, passed, with northwesterly wind, increasing to brisk and rapidly-falling temperature over this station at from 1.35 a. m. to 2.20 a. m., moving from northeast to southwest. Generally foggy, with variable brisk northwesterly wind, until noon. A second thunder-storm, with heavy rain and a small amount of large hail, passed over at from 2.34 p. m. to 3.40 p. m., advancing from north to south. Light rain and foggy weather, with variable brisk northerly winds, prevailed until midnight. Total amount of rain-fall during the day, 1.07 inches. Distant thunder-storms passed by the station at 2 p. m., one in the north and the other in the northwest.

July 6.—Foggy weather, with variable brisk northwesterly wind, until 9.15 a. m.; fair the remainder of the day. The wind, after moderating to fresh, veered at 4 p. m. to north and at 5.40 p. m. to northeast, increasing in the mean time to brisk again, but moderated to light toward midnight, after becoming a steady northeast wind. Temperature rising very slowly.

July 7.—Generally fair weather, with variable light and gentle northerly winds until 6.35 p. m. Foggy weather, with wind backing to southwesterly and increasing to fresh and brisk, until midnight. Temperature rising slowly.

July 8.—Brisk southwesterly wind and dense fog, with light rain at 6 a. m., until 11 a. m., when wind veered to northwest. Cloudy at noon. Foggy weather prevailed, with brisk and fresh northwesterly wind, until midnight. Temperature falling considerably. Total amount of rain-fall during the day, .03 inch.

July 9.—Wind veered to northeast at 2 a. m., with fair weather. Heavy cumulus clouds in the valleys below from 4 a. m. to 6 a. m. At 8.20 a. m. the wind, having moderated to light, veered to southeast, and calmed entirely at 10 a. m., but soon rose again and backed to northwest, remaining so until 2.45 p. m., when it veered to northeast and east, increasing in the mean time to fresh. Generally cloudy weather from 8.20 a. m. until 7.30 p. m., when fog settled upon the mountains. Light rain from 10.25 a. m. to 10.45 p. m. Temperature rising slowly. Total amount of rain-fall during the day, .02 inch.

July 10.—Easterly winds with light rain until 1.35 a. m.; shortly after 2 a. m. the wind veered to southwest, and the fog raised about 3 a. m., but settled again at 5 a. m. and remained until 10 a. m.; heavy rain at 11.45 a. m. Wind veered during the afternoon, with light showers, from southwest to south and to west, towards midnight increasing to brisk. Distant thunder-storms at 5 p. m. in south and southwest; heat-lightning in south and southeast horizon at 10 p. m. Fair weather from 8.35 p. m. until midnight. Temperature declining slightly. Total amount of rain-fall during the day, .50 inch.

July 11.—Foggy weather with brisk and steady westerly wind, until 5.40 a. m., when the wind veered to northwest and moderated to gentle; fair weather until noon; clear weather, with light northwesterly wind, until 6.25 p. m.; a calm occurred at 5 p. m. 6.25 p. m. the wind veered to northeast, and shortly afterward to east, increasing to fresh, and continued with foggy weather until midnight. Temperature rising.

July 12.—Foggy and cloudy weather until 3.40 a. m.; fair until 6.10 a. m., when

Digitized by Google

settled again; light rain from 8.50 until 10.10 a. m.; steady, brisk, and fresh easterly wind until 11.45 a. m., when wind veered to southeast; partly fair and cloudy weather until 6.30 p. m.; foggy with variable, brisk and fresh easterly wind until midnight. Temperature steady. Total amount of rain-fall during the day .07 inch.

July 13.—Foggy weather, with variable, fresh, and brisk southeasterly wind until 8.10 a. m.; fair until 8.40 p. m. At 12.20 p. m., the wind backed to east, and continued so until midnight. Foggy weather prevailed from 8.40 p. m. until midnight. Temperature steady.

July 14.—Foggy, with fresh southeasterly wind at the beginning of the day; at 1.35 a. m. the wind veered to southwest and the weather became fair, remaining so until 9.20 a. m.; cloudy weather with light showers until 5 p. m.; fair the remainder of the day; light and gentle variable westerly winds, with a calm at 1 p. m. until midnight. Temperature rising. Total amount of rain-fall during the day, .14 inch.

July 15.—Partly fair and foggy weather, with variable, fresh, and brisk northwesterly to northeasterly wind until 9.15 a. m.; cloudy until 4.25 p. m., when a heavy rain began to fall, with falling temperature and wind, which had somewhat moderated, increasing to brisk again. The rain continued, after moderating to light, until 7.15 p. m.; fair weather, with variable, brisk, and fresh northeasterly wind, prevailed until midnight. Total amount of rain-fall during the day, .31 inch.

July 16.—Generally fair and foggy weather, with variable, brisk, and fresh northeasterly wind, until noon, by which time the wind had moderated to light. At 12.10 p. m. the wind backed to northwest, and the weather became cloudy, remaining so until 4.20 p. m. Fair and foggy weather, with variable light and gentle northwesterly wind, and a calm at 7 p. m., until midnight. Temperature rising.

July 17.—Fair weather prevailed until 10.20 a. m.; cloudy until 6 p. m., from which time the weather continued fair until midnight; variable westerly wind until 3.40 a. m. The wind veered then to northwest, and became steady, moderating in force, and calmed at 4.14 p. m. A second calm at 7 p. m; afterward a variable southwest wind set in and continued until midnight, increasing gradually to brisk. Temperature rising.

July 18.—Fair weather at the beginning of the day, which by 2.15 a. m. became foggy and continued so until 9.40 a. m.; cloudy and rainy until 2.45 p. m; generally foggy weather then prevailed until midnight. Variable, fresh, and brisk southwesterly to northwesterly winds throughout the day. A distant thunder-storm passed by this station at 1 p. m. in the west, moving from south to north. Temperature falling. Total amount of rain-fall during the day, .38 inch.

July 19.—Generally foggy and cloudy weather, with fresh and brisk variable northwesterly and westerly winds and rapidly falling temperature, during the entire day, with the exception of the time between 5.40 a. m. to 6.10 a. m., and 5 p. m. to 5.05 p. m., when a light rain fell, and from 11.40 a. m. to 2.10 p. m., during which time the weather was fair, clearing toward midnight. Total amount of rain-fall during the day .03 inch.

July 20.—Generally cloudy weather, with fresh westerly winds and falling temperature, during the day. Foggy weather toward midnight. From 8 p. m. to 9 p. m. the wind had calmed entirely.

July 21.—Foggy and cloudy weather, with steady, fresh, and gentle west and northwest wind, until 3.40 p. m. Fair weather until midnight. At 9 p. m. the wind calmed and the sky was perfectly clear. Temperature still declining.

July 22.—Variable, gentle southerly winds and partially cloudy and fair weather until 10 a. m., when the wind backed to northeast and soon afterward to southwest; during the afternoon the wind veered to east and south, and at midnight to southwest. Generally foggy and cloudy weather until 9 p. m. and fair until midnight. Temperature rising slowly.

July 23.—Foggy and fair weather, with variable southerly to westerly winds, until 7.25 a. m., when the wind veered to northwest. Generally cloudy and fair weather, with occasional calms, until 10 p. m., when the weather became perfectly clear. Temperature rising.

July 24.—Clear weather until 3.30 a. m.; fair and foggy, with steady, gentle northwest wind until 8 a. m., when the wind veered to northeast, and finally to southwest. Cloudy and foggy weather, with occasional calms, until 9 p. m., when the weather became fair and clear by 10.39 p. m. At 10.14 p. m. the wind veered to northwest and north, and continued so until midnight. Temperature steady.

July 25.—Generally fair and cloudy weather, with variable and steady northwest to southwest winds, until noon. Foggy and rainy weather, with variable south and southwest wind, which increased to brisk by 8 p. m., until midnight. Temperature slightly falling. Total amount of rain-fall during the day, .24 inch.

July 26.—Foggy and rainy weather, with variable brisk and fresh southwest wind, until midnight. Temperature slightly rising. Total amount of rain-fall during the day, .19 inch.

July 27.—Foggy and cloudy weather until 10.30 a. m., when rain began to fall, and

Digitized by Google

continued with but little interruption until midnight. Steady and variable southwest wind prevailed during the day. Three thunder-storms passed during the day over this station; the first with light rain at 1 p. m., advancing from north to south; the second and third with heavy rain, moving from south to north, at 6.40 p. m. and 11.55 p. m. respectively. A distant thunder-storm passed by in the east at 6 p. m., moving from south to north. Temperature steady. Total amount of rain-fall during the day, 1.[illegible] inches.

July 28.—Rainy and foggy weather until 7.45 a. m., when the weather became cloudy, remaining so until 3.39 p. m., when a heavy rain began to fall, ending at 5.32 p. m. Foggy weather during the remainder of the day. Variable, fresh, and brisk westerly winds prevailed throughout the day. Three thunder-storms passed over this station during the day; the first, with heavy rain, at 1 a. m., moving from south to north. The second and third thunder-storms followed each other in short succession from 3.39 p. m. to 5.32 p. m., moving from southeast to northwest, during the passage of which the greatest amount of rain fell so far here on record, amounting to .99 inch within 1 hour and 53 minutes. Temperature steady. Total amount of rain-fall during the day, 1.49 inches.

July 29.—Generally fair and cloudy weather, with steady northwest wind and slightly diminishing temperature, prevailed throughout the day.

July 30.—Fair and foggy weather until 7.35 a. m. Cloudy until after 10 a. m. At 11.25 a. m. light rain began to fall, and continued with little interruption until 3.45 p. m. Generally foggy and cloudy weather until 11.20 p. m. Fair at midnight. Steady northwest wind prevailed until 7.20 a. m., backing then in short succession to west, southwest, south, southeast, and finally east, until noon, and continued a variable southerly wind with increasing force until midnight. Temperature rising. Total amount of rain-fall during the day, .31 inch.

July 31.—Fair weather until 8.15 a. m. Generally foggy and cloudy weather prevailed the remainder of the day. Light rain fell from 1.15 p. m. to 2.55 p. m. Light to fresh southerly winds until 6.20 p. m., when the wind veered to northwest, and increasing to brisk continued until midnight. Temperature steady. Total amount of rain-fall during the day, .27 inch.

Abstract of journal for the month of August, 1873; *station, summit of Mount Mitchell, North Carolina.*

August 1.—Generally foggy and cloudy weather, with steady temperature and northwest and west winds, which until noon were variable and mostly brisk, but became steady and fresh during the remainder of the day, prevailed throughout the entire day.

August 2.—Fair weather in the earlier morning. Generally foggy and cloudy until after 8 p. m., when the weather became fair and remained so until midnight. Light rain from 6.50 a. m. to 7.45 a. m. Steady fresh northwest wind prevailed throughout the day. Temperature slightly falling. Total amount of rain-fall during the day, .[illegible] inch.

August 3.—Generally fair and cloudy weather, with rising temperature and steady fresh northwest wind, prevailed throughout the day. Light rain fell from 6.33 p. m. to 6.48 p. m., and from 7.20 p. m. to 7.40 p. m. A distant thunder-storm passed by this station, in the south, at 3 p. m., moving from southwest to northeast. Total amount of rain-fall during the day, .07 inch.

August 4.—Fair weather, with variable westerly winds, until 7.35 a. m. Generally foggy and rainy weather until midnight. Temperature slightly falling. Total amount

Digitized by Google

of rain-fall during the day, .55 inch. Thunder-storm at 2.20 p. m., moving from west to east.

August 5.—Foggy weather, with variable easterly winds and falling temperature, throughout the entire day.

August 6.—Generally foggy weather, with variable easterly winds, until 9.15 p. m., when the wind veered to south and the weather became fair. Temperature low for the season.

August 7.—Generally foggy and cloudy weather, with variable south and west winds, throughout the day. Temperature rising.

August 8.—Fair weather prevailed until 4.20 a. m., when fog settled on the mountains and continued until midnight. Light rain fell from 9.10 a. m. until 9.40 a. m., and partly heavy and light rain from 4.25 p. m. to 5.10 p. m. Steady, fresh, and brisk northwest wind prevailed throughout the day. Temperature slowly rising. Total amount of rain-fall during the day, .43 inch.

August 9.—Generally foggy weather, with heavy rain from 2.15 p. m. until 9.15 p. m., when the weather became fair. Generally brisk and fresh, steady and variable northwest wind prevailed during the day, moderating to light by midnight. Temperature rising but slowly. Total amount of rain-fall during the day, .20 inch.

August 10.—Fair weather continued until 10.15 a. m. Cloudy until noon. At 1 p. m. light rain began to fall, increasing to heavy during the passage of a thunder-storm, which moved from east to west over this station at 2 20 p. m. Cloudy and foggy until 7.32 p. m. Partly heavy and light rain from 7.32 p. m. until 10.30 p. m., clearing toward and at midnight; steady, gentle, and fresh northwest wind until 10.40 a. m., when the wind veered to northeast and continued a variable easterly wind until midnight. Temperature steady. Distant thunder-storms in southwest from 2.30 to 3.15 p. m. Total amount of rain-fall during the day, 1.17 inch.

August 11.—Fair weather until after 8 a. m. Generally foggy and cloudy, with heavy rain from 4.25 p. m. to 4.40 p. m., until 6.20 p. m. Fair during the remainder of the day. Variable, gentle, and fresh northeast to south winds throughout the day. Temperature falling. Total amount of rain-fall during the day, .15 inch.

August 12.—Fair weather continued until 8.25 a. m. Cloudy until 7.30 p. m. Foggy the remainder of the day. Gentle and fresh variable westerly winds prevailed throughout the day. Temperature rising. During the afternoon three distant thunder-storms passed by this station, viz, at 2 p. m. in the southwest, at 5 p. m. in the northwest, and at 6 p. m. in northeast.

August 13.—Light rain in the early morning from 12.25 a. m. to 12.40 a. m. Foggy until 6.25 a. m. At 6.25 a. m. a very severe thunder-storm with heavy rain passed over this station, advancing from north to south. Heavy rain continued until 1.15 p. m. Clearing at 3 p. m., but clouding over by 4.20 p. m. Foggy from 6.48 p. m. until midnight. Temperature falling rapidly during the passage of the thunder-storm, and remaining low during the remainder of the day. Variable fresh westerly winds prevailed throughout the day. Total amount of rain-fall during the day, 1.90 inch.

August 14.—Foggy weather until noon, when the fog slowly disappeared. Sky covered with heavy cumulus clouds until after 5 p. m. Fog again then settled upon the mountains. Shortly after 10 p. m. the fog nearly disappeared, revealing a cloudless sky, and remaining so until midnight. Temperature low and falling. Variable, brisk, and fresh west and northwest winds prevailed throughout the day.

August 15.—Foggy weather, with showers of light rain from 8.30 a. m. to 8.50 a. m., and from 9.50 a. m. to 10.10 a. m., until noon, when the fog disappeared, disclosing the sky covered with heavy cumulus clouds. Fair weather prevailed from 5.20 p. m. until midnight. Temperature low, but slowly rising. Variable westerly winds throughout the day. Total amount of rain-fall during the day, .06 inch.

August 16.—Generally fair until 8.25 a. m., when the weather became cloudy, remaining so until 3.40 p. m. Foggy during the remainder of the day. Fall of light rain from 3.10 p. m. to 4.03 p. m. and from 6.15 p. m. to 6.40 p. m. Temperature rising considerably. Variable fresh westerly winds, which moderated to gentle and light from 11 a. m. until after 6 p. m. and increased then again to fresh, prevailed throughout the day. Total amount of rain-fall during the day, .04 inch.

August 17.—Foggy weather continued until 10.35 a. m., when a light rain began to fall, ending at 11.08 a. m. Generally foggy and cloudy until 1.32 p. m. Partly heavy and light rain until 3.25 p. m., clearing at 4.14 p. m., but clouding over shortly afterward. Light rain again fell from 8.35 p. m. until 9.11 p. m. Foggy the remainder of the day. Distant thunder-storms at 2 p. m. in south, at 8 p. m. in west, and at 9 p. m. in southwest. Heat-lightning around the whole horizon from 7 p. m. to 7.45 p. m. Variable fresh and gentle east to south winds until noon; variable fresh south to southwest winds until midnight. Temperature slightly rising. Total amount of rain-fall during the day, .40 inch.

August 18.—Foggy weather, with heavy rain from 1.10 a. m. to 1.35 a. m., until shortly after 8 a. m., when the weather became cloudy, remaining so until 2 p. m., with the exception of the time from 10.40 a. m. to 11.06 a. m., during which light rain fell. At

Digitized by Google

2 p. m. light rain then began to fall, becoming heavy at 2.10 p. m. during the passage of a thunder-storm, which advanced slowly from west to east, and moderated again at 2.53 p. m. The rain ended at 5.15 p. m.; cloudy until after 8 p. m.; fair the remainder of the day. Variable fresh and brisk south and southwest winds until 2 p. m., when the wind veered to northwest and moderated to gentle, but increased to brisk and veered to north during the passage of the thunder-storm, after which the wind backed to west and remained so, moderating to light, until midnight. Temperature rising until 2 p. m., but falling rapidly until 3.10 p. m., when it rose slightly and became steady. Total amount of rain-fall during the day, .70 inch.

August 19.—Generally fair weather until 7.30 a. m.; cloudy until noon; foggy, with fall of light rain from 3.25 p. m. to 4.45 p. m., and of heavy rain from 6.38 p. m. to 7.[illegible] p. m., until midnight. Temperature slightly falling. Variable gentle and light westerly and easterly winds, with occasional calms until after 3 p. m., when the wind veered to north and northeast and increased to fresh, remaining so until midnight. Total amount of rain-fall during the day, .54 inch.

August 20.—Heavy rain at the early beginning of the day. Fair and foggy, with light rain from 10.05 a. m. to 10.20 a. m., until noon. Generally foggy, with very heavy rain, until midnight. Temperature steady. Generally variable light to fresh easterly wind, with occasional calms during the forenoon, prevailed throughout the day. Total amount of rain-fall during the day, 2.08 inches.

August 21.—Generally foggy and cloudy weather prevailed, with light rain-fall from 2.30 p. m. to 2.40 p. m., and 4.20 p. m. to 4.50 p. m., throughout the day. Variable fresh southeast to west winds, with a calm at 2 p. m., during the entire day. Temperature rising. Total amount of rain, fall during the day, .16 inch.

August 22.—Generally cloudy and fair weather until 9.10 a. m., foggy until 10.46 a. m. when light rain began to fall, increasing soon to heavy and ending at 11.36 a. m. Light rain during the greater part of the afternoon. Cloudy until 10.15 p. m. Fair until midnight. A thunder-storm, with light rain, passed over at 3 p. m. moving from northwest to southeast. Steady westerly winds until 10 a. m. Variable fresh northeast wind until midnight. Total amount of rain-fall during the day .25 inch.

August 23.—Fair weather in the morning, cloudy during the forenoon and afternoon, fair until midnight. A distant thunder-storm passed by at 2 p. m. in the northeast. Light rain from 3 p. m. to 3.25 p. m. Variable east to northwest winds throughout the day. Temperature rising. Total amount of rain-fall during the day, .03 inch.

August 24.—Generally fair weather, with rising temperature and light to fresh north to northwest winds, with occasional calms, prevailed throughout the day.

August 25.—Fair weather continued until after 3 p. m. Partly foggy and cloudy during the remainder of the day. Light rain-fall from 6.30 to 6.50 p. m. Temperature still rising. Variable westerly winds prevailed until 6.30 p. m., when a steady, brisk northwest wind set in and remained so until midnight. Total amount of rain-fall during the day, .03 inches.

August 26.—Partly foggy and cloudy weather during the entire day, with the exception of the time from 6.40 p. m. to 7.20 p. m. when a heavy rain fell. The fresh and brisk northwest wind continued steady until midnight. Temperature falling slowly. Total amount of rain-fall during the day, .11 inch.

August 27.—Foggy and cloudy weather until 8.30 a. m., when it became fair, but cloudy again shortly after 1 p. m., remaining so until midnight. Distant thunder-storms at 9 p. m. in west and north and at 3 p. m. in southeast and east. Temperature falling. Steady fresh and brisk northwest wind until after 1 p. m., when the wind backed to west and moderated to gentle, but increased to fresh by midnight.

August 28.—The weather continued foggy until 5.57 p. m., when a light rain began to fall, ending at 8.10 p. m., after which the weather became fair, but was foggy again by midnight. Variable southwest to east winds throughout the day. Temperature falling considerably. Heat-lightning on western horizon at 9 p. m. The singular phenomenon of a fog-bow of great brilliancy, caused by the moon, was observed at 10 p. m. Total amount of rain-fall during the day, .34 inch.

August 29.—Generally fair and foggy until 8 a. m.; cloudy until 4.25 p. m.; partly fair and cloudy until midnight; variable southwest to northwest wind prevailed during the day. Temperature steady. Light rain-fall from 3.15 p. m. to 3.40 p. m. Distant thunder-storm at 3 p. m. in the west. During the latter part of the afternoon the valleys were filled with heavy cumulus clouds. Total amount of rain-fall during the day, .06 inch.

August 30.—Fair weather at the beginning of the day, foggy until 10.30 a. m.; cloudy until shortly after 5 p. m.; generally fair the remainder of the day. Clear at midnight. Variable fresh to brisk westerly winds prevailed throughout the day. Temperature steady.

August 31.—Fair weather continued until 5.25 a. m., when a dense fog settled on the mountains, remaining so until shortly after 8 a. m.; cloudy until 3 p. m.; fair the remainder of the day. Variable and steady westerly winds prevailed throughout the day. Temperature rising.

MONTHLY SUMMARY.

Mean temperature during August	55°.3
Highest observed temperature	69°.
Lowest observed temperature	43°.
Total amount of rain-fall	9.34 inches.
Number of rainy days	21
The prevailing winds were from	N.W.
Number of miles traveled	6,156

Instruments in use are all in good condition.

September 1.—Partly fair and cloudy weather, with rising temperature and light to fresh variable westerly winds, throughout the day.

September 2.—Generally cloudy until 3.35 p. m., when a heavy rain began to fall, ending at 6.20 p. m.; foggy until 9.20 p.m.; fair until midnight. Variable gentle to fresh westerly winds prevailed throughout the day. Temperature slightly falling. Total amount of rain-fall during the day, .52 inch.

September 3.—Generally foggy and cloudy weather with steady temperature and variable southeast to southwest and west winds, which shortly after 6 p. m. became brisk throughout the day. Light rain fell from 2 p. m. to 2.35 p. m. Heat-lightning at 7 p. m. on northeastern horizon. Total amount of rain-fall during the day, .03 inch.

September 4.—Partly foggy and cloudy weather, with falling temperature and brisk variable and steady southwest to northwest winds, throughout the day. Fall of light rain from 10.15 a. m. to 10.50 a. m. Total amount of rain-fall during the day, .09 inch.

September 5.—Foggy weather, with slightly rising temperature, and variable brisk southwest to northwest wind throughout the day. Light rain fell from 12.35 p. m. to 1.35 p. m., and heavy rain from 3.20 p. m. to 4.05 p. m., during which time the wind veered suddenly to northeast, but backed to northwest after the rain ended. Distant thunder-storm at 6 p. m. in the north. Total amount of rain-fall during the day, .28 inch.

W. E. SMITH,
Observer-Sergeant Signal-Service, U. S. A.

G.

Abstract of journal for the month of August, 1873.

BASE OF MOUNT MITCHELL, YANCEY COUNTY, NORTH CAROLINA.

July 29, 1873.—Arrived at "Old Fort," McDowell County, North Carolina.

July 30.—Proceeded to summit of Mount Mitchell, compared barometer with those at that station, and selected site for base station.

July 31.—Returned to "Old Fort."

August 2.—Started for "Toe River Valley," in a wagon drawn by three mules, traveled thirty miles, and laid over for the night at the base of the Blue Ridge Mountains.

August 3.—Crossed the "Blue Ridge" and arrived at site of station at 10 p. m.

August 4.—Commenced to put instruments in position. Worked hard all day.

August 5.—Everything in readiness except the "Daniells" battery for self-registering anemometer, which is not yet in order.

Comparative readings of barometers Nos. 185 *and* 1915, *taken on the summit of Mount Mitchell July* 30, 1873.

Summit barometer, (No. 185.)			Base barometer, (No. 1915.)		
Time.	Barometer.	Attached thermometer.	Time.	Barometer.	Attached thermometer.
10.40 p. m	23.87	63	10.40 p. m	23.89	63
10.50 p. m	23.88	63	10.50 p. m	23.89	64
11.00 p. m	23.86	62	11.00 p. m	23.88	63
11.10 p. m	23.86	62	11.10 p. m	23.89	63
11.20 p. m	23.87	62	11.20 p. m	23.89	62
11.30 p. m	23.87	62	11.30 p. m	23.88	62
11.40 p. m	23.86	63	11.40 p. m	23.88	63

Digitized by Google

The difference of the readings of the two barometers cannot be noted, owing to the summit station not being furnished with the instrumental error of barometer No. 185.

August 6.—The barometer has fluctuated some during the day. An increase of pressure was shown from 6 to 9 a. m., but fell off .08 by 5 p. m., and increased slightly from that time until midnight, giving a mean of 27.517. The thermometer read 60° at 1 a. m., sank gradually until 5 a. m., when the column began to ascend and attained a maximum of 80° at 12 o'clock, (noon,) decreased during the afternoon, and finally reached a minimum at 54° at 12 p. m. Mean thermometer, 64°.2. Humidity ranged between 54 and 94 per cent. With the exception of a light easterly wind, from 8 a. m. to 2 p. m., the atmosphere has remained perfectly calm. About one-half of the sky was covered by stratus clouds at 1 a. m.; they, however, disappeared at 2 a. m., only to re-appear at 3 a. m. and remain throughout the day, varying in amount from one to three-fourths, and completely covering the sky at last observation. Cumulus and cirrus clouds were observed during the day; the latter having a great elevation and being very beautiful.

August 7.—The barometer sank unevenly from 27.48 at 1 a. m. to 27.36 at 5 p. m., and then began to rise, and continued until midnight. Daily mean barometer, 27.426. The minimum temperature, 55°, was shown at 1 a. m.; the mercury then began to ascend slowly, and after 7 a. m. accelerated its pace, and attained a maximum of 76° at 10 a. m.; decreased regularly and slowly the rest of the day. Daily mean thermometer, 66°.2. Humidity ranged from 63 to 95 per cent., being greatest during the night hours. A calm has prevailed throughout the entire day. Stratus clouds covered the sky at 1 and 2 a. m., having a motion from the south; by 3 a. m. they had partly disappeared, but soon formed again, rendering it cloudy at 4 a. m.; they broke up shortly after, and began to move off from the southwest, being invisible at 5.30 a. m. Cumulus clouds now appeared, having a slow motion toward the northeast. Cirrus clouds formed after 7 a. m., greatly elevated; several forms of the "curl clouds" were observed, the "horse-tails" and "twisted tufts" being the most numerous. Stratus clouds formed again at 9 a. m., and continued the remainder of the day, varying in amount from one to four fourths. Cumulus and cirrus clouds were seen during the day, their motion being from the west. Some very well-defined cirro-cumulus clouds were observed at 10 and 11 p. m.

August 8.—The barometer increased a little from 1 to 9 a. m., at which time the maximum reading of the day occurred, and then began to decrease, and continued slowly until 5 p. m., having then fallen .07; from that time until midnight its course was marked by fluctuations, but the last reading shows a slight gain. Mean daily barometer, 27.375. A steady temperature of 60° was shown by the thermometer, between the hours of 1 and 4 a. m.; after the latter hour the column began to ascend and attained a maximum of 77° at 1 p. m.; during the afternoon and evening the mercury sank evenly, and finally dropped to 60° again. Mean daily thermometer, 65°.2. Humidity ranged from 73 to 100 per cent. Gentle westerly winds were felt at the hours of 1, 4, and 5 p. m., the remainder of the day being perfectly calm. A fog arising from the river enveloped the station from 1 to 3 a. m., but dissipated soon thereafter. Stratus clouds covered the sky at 4 a. m. and as the morning advanced assumed a threatening appearance, which was verified by a rain, varying from light to heavy, commencing at 8.25 a. m., and continuing at intervals until 11.25 a. m.; commenced to clear up shortly after the rain ceased; the stratus clouds moved off from the west and disappeared. Large masses of white cumulus clouds now put in an appearance, moving slowly from the west, accompanied by a few silvery cirrus clouds floating at a great height in the air, and moving much slower than the cumulus clouds. Stratus clouds partly covered the sky at 2 p. m., increasing until rain descended, at 4.45 p. m., lasting only a short time. A few stratus clouds were visible during the evening, and above them about one-fourth cirrrus clouds, which at one time assumed the cirro-stratus formation. A fog commenced to rise at 10 p. m., and at 11 p. m. all was hidden. Whole amount of rain collected during the day, .05.

August 9.—The pressure of the air, as shown by the barometer, increased slightly during the morning until 9 a. m., and then began to decrease, going down regularly until 5 p. m., when it began to rise, and continued advancing the rest of the evening. Mean barometer, 27.371. A minimum temperature of 60° was shown from 1 to 3 a. m., and then the mercury commenced to rise at the rate of one degree per hour until after 6 a. m., when it rose rapidly—the 7.14 a. m. showing a rise of six degrees, and the 8 a. m. a rise of 10° since last observation. After 8 a. m. and until 3 p. m. the column fluctuated considerably between 77° and 80°, the latter number being the maximum, and was read at 11 a. m. and again at 1 p. m. At 4 p. m. the temperature began to decline, and was still falling at last observation. Mean temperature, 69°.5. The percentage of humidity was very large, being above 90 per cent. for thirteen hours of the day. The atmosphere was perfectly calm until 7.30 a. m., when a gentle wind sprung up from the northeast, and continued steady in that direction for six and a half hours, being the longest time that wind has been felt since the establishment of the station. Calmed

Digitized by Google

again at 3 p. m., and remained so for the rest of the day. Stratus clouds, having a tardy motion from the west, covered the sky at 1 and 2 a. m. A fog then began to rise from the river and sides of the mountains, and soon hid every object from view, which continued until after 4 a. m., when it began to ascend, forming four-fourths stratus at 5 a. m., and dissipating shortly after 6 a. m. Cumulus clouds now formed and remained, looking majestic and grand, the greater part of the day. A shower of rain fell between 3.10 and 3.40 p. m. Stratus clouds were seen again at 4.30 p. m., and continued visible the rest of the evening, varying in amount from one to four-fourths, and moving slowly from the west and north. Another shower of rain fell from 7.20 to 8.30 p. m. Cirro-cumulus clouds were seen at 9 and 11 p. m., but were not well defined. A fog formed and hid everything at 12 p. m. Amount of rain collected during the day, .08. A very heavy dew has been deposited every night during the past week.

August 10.—The barometer has fluctuated continually to-day, the oscillations being comprehended between 27.38 and 27.43. Mean barometer, 27.390. The thermometer was unsteady in the early part of the morning, falling off from 63° at 1 a. m. to a minimum of 59° at 5 a. m. After 6 a. m. it began to rise, and acquired a maximum of 81° at 11 a. m. and fell 10° within the next hour, (rain falling at the time,) commenced to rise again at 1 p. m. and continued slowly until 5 p. m., when it began to sink, going down gradually to 60° at 12 p. m. Mean thermometer, 69°.1. Calm from 1 to 3 a. m., and then a light northeaster was felt, but soon died away. A light northwest breeze set in at 9 a. m., but changed to northeast at 10 a. m., and remained in that direction until after 4 p. m., when it calmed again. A gentle north wind sprung up about 7 p. m., changing to northwest at 7.30 p. m., and kept that direction until 10.20 p. m. and then grew calm. The fog reported in my journal at 12 p. m. of yesterday still continues this morning, and, if possible, grows more dense. After 4 a. m. it partly cleared off and revealed about one-fourth cirrus clouds, and soon after 6 a. m. had entirely disappeared. Cirro-cumulus clouds were then seen moving from the west. Cumulus clouds soon succeeded the compound combination, and, from the intense heat of the sun, rose up in large, rounded, beautiful masses, which covered the sky at 11.30 a. m. A thunder-storm commenced very suddenly at 11.35 a. m., and soon the rain became general and the valley filled with rain-clouds. Rain ceased at 12.30 p. m. Stratus clouds were visible during the greater part of the remainder of the day. Cumulus, cirrus, and cirro-cumulus were also seen moving from some northerly point until hidden by stratus clouds at 6.20 p. m. A light shower of rain fell from 6.38 p. m. to 6.55 p. m. Commenced again, very heavy, at 7.25 p. m., the water at times coming down in torrents. Rain ended at 9.46 p. m., and the clouds began to clear off and at 11.30 p. m. had all disappeared, but a fog commenced to form and was fast covering objects at last observation.

August 11.—The barometrical column oscillated some to-day, but the fluctuations are not such as to call for special remark. Daily mean barometer, 27.372. The thermometer was steady at 61° and 60° until after 6 a. m., when it began to increase and went up to a maximum of 76° at 11 a. m., and sank gradually to a minimum of 59° at 12 p. m. Mean daily temperature, 67°.7. The humidity to-day has been great; the hygrometer indicated 100 % at 6 a. m. Calm from 1 to 8.30 a. m.; a gentle breeze then set in from the southeast, and kept steady at that point until 3.15 p. m., and from that time until after dark there ensued a succession of calms and light east winds, but finally calmed at 9 p. m., remaining so at last observation. A dense fog hung over the station until 6 a. m., and then began to lift, and as it ascended dissipated and had entirely dissolved at 7 a. m. Stratus clouds were seen for a few hours after sunrise, and also a few cirrus and cumulus. The stratus and cirrus clouds had all disappeared at 9.30 a. m., leaving lofty cumulus clouds, varying in amount from one to two fourths, and moving for a couple of hours from the southeast, but changed direction to northwest at 1 p. m. and to south at 2 p. m. Stratus clouds now formed, and with the cumulus clouds increased until the sky was overcast, at 5 p. m. Stratus clouds continued increasing, hiding the upper clouds, and presented a threatening appearance soon after sunset. A light rain fell about dark; the amount collected being too small for measurement. Cleared up soon after the shower; the stratus clouds moved off from the southeast, revealing one-fourth cirrus clouds, progressing slowly toward the east. A perfectly clear sky was observed at 9 p. m., the moon and stars shining brightly. About one-fourth cumulus clouds formed a little before 10 p. m., but soon passed over from the south, and shortly after cirrus clouds, greatly elevated, and moving the opposite direction to that of the cumulus clouds, were seen. At midnight ill-defined cirro-cumulus clouds, having the appearance of the shorn side of a fleece of wool, were noticed moving from the southwest. At the same time a long line of fog could be seen lying close to the base of the mountains, and encircling the whole valley. A halo around the moon was first noticed at 10.45 p. m., the color being of a faint yellow or straw color, the outer edges being tinged with a pale red.

August 12.—The barometer fluctuated between 27.35 and 27.37 until 9 a. m., and then commenced to fall and sank quite rapidly to 27.28 at 3 p. m., oscillating between that height and 27.31 the rest of the day. Mean barometer, 27.324. The thermometer exhibited its minimum of 57° at 2 a. m., and increased to a maximum of 79° at 11 a. m.,

Digitized by Google

and after fluctuating some hours in the seventies decreased to 64° at midnight. Mean thermometer, 67°.9. Humidity ranged between 61 and 94 per cent. A calm from 1 to 9 a. m. was succeeded by a light east wind, which lasted until after 3 p. m., being, however, interspersed with short calms. A dead calm took place at 4 p. m., the atmosphere remaining in this condition at last observation. A fog hid all objects, except those in close proximity, until 6 a. m., clearing off then, and at 7 a. m. a few stratus and cirrus clouds were seen, the cirrus clouds moving from the northwest. These clouds soon disappeared and gave place to cumulus clouds, having a slow motion from the northwest, and increasing until they covered the sky. Rain to the amount of .09 fell between 3.55 p. m. and 4.30 p. m.; stratus clouds varying in amount from one to four fourths were observed from that time until last observation.

August 13.—The barometer continued sinking unevenly throughout the entire day. Mean barometer, 27.223. The thermometer was steady at 64° from 1 to 6 a. m.; advanced very slowly to a maximum of 73° at 2 p. m., and sank evenly to a minimum of 55° at midnight. Mean thermometer, 64°.5. Humidity ranged between 67 and 94 per cent. Calms and light easterly and northeasterly winds succeeded each other throughout the day. Dark, gloomy-looking stratus clouds hung over the valley, and as the morning advanced grew more heavy and threatening, took up a rapid motion from the west and approached nearer the earth. Rain began at 5.05 a. m., and fell rather heavy at times, ceasing at 9.30 a. m. Another shower fell between 10.55 and 11.10 a. m. Stratus clouds cleared off after 1 p. m. and cirrus clouds put in an appearance, moving from the southwest. Stratus, cirrus, and cumulus clouds were visible until 6.30 p. m., when they disappeared, leaving a clear sky. Whole amount of rain, .94.

August 14.—The barometer decreased irregularly to-day. Mean barometer, 27.188. The temperature has been rather unsteady, reading 53° at 1 a. m.; fell to a minimum of 51° at 3 a. m. Commenced to rise at 4 a. m. and went up suddenly twelve degrees between 6 and 7 a. m., then reading 70°, which was the maximum of the day. After this it fell off to 67° and 68°, but at noon reached the maximum point again and remained there for three hours, and then decreased to 57° at 7 p. m.; it fluctuated between 57° and 59° the rest of the day. Mean temperature, 61°.2. Calm the first three hours of the morning, and then a light northeast wind set in, changing at 9 p. m. to north, in which direction it remained until 5 p. m. and then calmed, lasting two hours. For the remainder of the day there ensued a succession of calms and light north and northeast winds. Clear at 1 a. m., but a fog began to rise from the river and sides of the mountains, hiding everything at 2 a. m. At 3 a. m. it began to rise, forming as it ascended large cumulus clouds, which covered three-fourths of the sky at 4 a. m., and took up a motion from the northwest, disappearing to the southeast. Stratus formed soon after, increased to three-fourths, and were also moving from the northwest, while the upper atmosphere grew hazy. Stratus and cumulus clouds were observed during the greater portion of the day, the cumulus moving from the northwest, while the atmosphere at station was tranquil, or passing gently from the north.

Received a set of signal equipments and three original records to-day.

August 15.—The barometrical column has been in continual motion to-day, rising and falling alternately; the last observation, however, shows an increase of .08. Mean barometer, 27.187. The temperature increased steadily until 9 a. m. and then remained motionless until noon, advancing then, attaining a maximum of 72° at 2 p. m., and sinking gradually to a minimum of 53° at midnight. Mean thermometer, 64°.5. Humidity ranged between 65 and 94 per cent. A calm at 1 a. m. was succeeded by a northerly breeze at 2 a. m., which calmed at 3.30 a. m., only to be broken by a light north wind at 4.15 a. m., which kept steady at that point until 4.30 p. m., and then calmed, remaining so at 12 p. m. Two-fourths stratus and one-fourth cumulus clouds with fair weather are reported at 1 a. m., but soon became cloudy as the stratus clouds increased and covered the entire sky at 2 a. m., having a slow motion from the northwest. A break in the stratus clouds at 4 a. m. revealed about one-fourth cumulus clouds moving slowly from the north; the stratus soon closed up again and remained so until rain began to descend at 7.10 a. m., lasting until 7.38 a. m. Stratus clouds began to disappear about 10.30 a. m., and soon were lost to view; the sky filled up with cumulus clouds which were now moving from the west. All clouds cleared away about sunset, affording a remarkably clear night.

August 16.—The barometer was steady until 4.30 a. m. and then commenced to rise, and continued until 2 p. m. For the next three hours it sank .08 and advanced from that time until 12 p. m. Mean barometer, 27.248. The thermometer declined regularly from 53° at 1 a. m. to a minimum of 49° at 6 a. m., (this being the lowest reading since the establishing of the station;) for the next three hours the column went up rapidly, reading respectively 6°, 7°, and 9° higher than the observation preceding. The maximum, 75°, was shown at 11 a. m., and, after fluctuating between that point and 73° for the next two hours, declined evenly to 63° at last observation. Mean thermometer, 63°.9. A calm existed during the early morning, but was broken by a light west wind at 5 a. m.; calmed soon after, and during the remainder of the day there were alternately calms and light north winds. A fog had settled over the valley

Digitized by Google

and hid everything at 1 a. m.; at 5 a. m. it broke up and discovered one-fourth cirro-cumulus clouds moving rapidly from the west, and increasing to two-fourths by 6 a. m., and soon after disappeared. The fog as it ascended resolved itself into cumulus clouds, which were visible the greater portion of the day, varying in amount from one- to four-fourths, and were moving from the west while the lower atmosphere grew hazy. About 4 p. m. the cumulus clouds grew heavy, closed up, sank down the mountains, close to the earth in the valley, forming a complete veil. Rain commenced at 6.55 p. m., and ceased at 7.10 p. m., the amount being too small for measurement. Stratus clouds were seen during the rest of the evening covering the entire sky.

August 17.—The barometer was almost motionless from 1 to 5 a. m. and then began to rise. At 10.30 a. m. the advance was checked, and in a short time the column began to sink, continuing until 6 p. m., and after rising for a couple of hours remained stationary until midnight. Mean barometer, 27.311. The thermometer stood at 62° at 1 a. m., but dropped to a minimum of 60° at 2 a. m., and held that point until 6 a. m.; commenced to rise rapidly, reaching 76° at 9 a. m.; fell to 74° by 9.30 a. m., and kept that height until 11 a. m., when it again ascended, reaching a maximum of 77° at noon. Between 1.40 and 2 p. m., while a shower of rain was falling, the column sank seven degrees. At 3 and 4 p. m. it read 72° and sank evenly to 61° at last observation. Mean thermometer, 67°.1. No air was stirring, except a light north and northeast wind at 8 and 9 a. m. until 11.30 a. m., when a gentle breeze was felt from the south, remaining steady in that direction until 4.30 p. m.; it died away and continued calm at 11 p. m. The clouds have been very changeable to-day. Cirrus, cirro-cumulus, and stratus clouds are reported at 1 and 2 a. m., the upper clouds moving from the west while the stratus clouds were progressing toward the southeast, and increased, hiding the upper atmosphere at 3 a. m., but opened soon after, revealing the upper clouds and disappearing at 8.30 a. m. Cirro-cumulus were visible until after 10 a. m. Cumulus formed about 8.40 a. m., and went on increasing until rain descended, between 11 a. m. and 12 m. A heavy shower fell between 1.40 and 2.45 p. m. Cumulus and cirrus clouds were observed until 6.30 p. m., and then cleared away, leaving a haze in the upper regions. A few stratus clouds were visible at 8 p. m., which grew heavy, and rained for a short time, the balance of the sky being free from clouds. Whole amount of rain collected during the day, .28.

August 18.—The barometer has been constantly in motion during the day, but the fluctuations did not exceed .04. Mean barometer, 27.311. The temperature was steady at 61° and 63° until 7.30 a. m., and then advanced evenly to a maximum of 75° at noon, and after 1 p. m. fell off evenly to a minimum of 60° at 9 and 10 p. m. Mean thermometer, 65°. The percentage of humidity has been high, ranging from 72 per cent. to 100 per cent. A continued calm was broken by a gentle north wind at 9 a. m., which changed to south-southeast and back to north again in the next few hours. Calmed about sunset and remained so at last observation. Cloudy and rainy weather has been reported all day, the showers being frequent and some of them very heavy. Total rain-fall, .94.

August 19.—To-day's barometric readings are confined between 27.29 and 27.35. Mean barometer, 27.317. The thermometer sank from 61° at 1 a. m. to a minimum of 58° at 4 a. m. and remained at that height until after 6 a. m., when it ascended evenly to a maximum of 73° at noon, and then fell off gradually to 63° at midnight. Mean thermometer, 65°.1. The calm reported at midnight of yesterday continued until broken by a light southwest wind at 2 a. m., calmed again at 5 a. m., and remained so for the balance of the day. The sky has been completely covered by clouds (principally stratus) during the entire day. Rain commenced shortly after sunset and continued at intervals throughout the evening. Amount of rain-fall, .54.

August 20.—The barometer was steady at 27.30 and 27.32 until 6 a. m., when it began to ascend, rising to 27.35 at 9 a. m. Here the advance was checked, the column began to sink, and at 1 p. m. read 27.30. Again for the next four hours no motion was perceptible. After 6 p. m. it showed a tendency to increase, and was progressing slowly at 12 p. m. Mean barometer, 27.326. The temperature varied from the minimum, 61°, to 64° between 1 and 6 a. m., and then increased steadily to a maximum of 75° at noon and fell off gradually to 64° at midnight. Mean thermometer, 67°. No wind was perceptible until 10 a. m., when a light breeze was felt, varying in direction from east to northeast and calming at 3 p. m., in which condition the atmosphere remained, with the exception of a slight motion from the east at 8 p. m., until midnight. The weather to-day has been rather unsettled. Frequent showers fell during the day, and in the evening, from 6.20 to 10.10 p. m., we had a continued light rain. Whole amount of rain-fall, .35.

August 21.—The barometer increased steadily from 1 to 9 a. m. and then decreased in the same proportion until 2 p. m., after which there was not much change until 5.30 p. m., when it began to ascend and continued so at last observation. Mean barometer, 27.358. The thermometer stood at 62° and 63° in the early morning and then went up to a maximum of 75° at 11 a. m., and fell off gradually to a second minimum of 62° at midnight. Mean thermometer, 67°.1. A calm prevailed during the day, broken occa-

Digitized by Google

sionally by scarcely perceptible east winds. The weather to-day has been rather mixed. Stratus clouds began forming about 1 a. m. and went on increasing, covering the sky at 4 a. m. Shortly after they began to dissipate and were invisible at 7 a. m. Cumulus clouds began to form as the stratus retired, increased to three-fourths, and moved slowly from the north and northwest; suddenly they changed direction and moved from the southwest; at the same time stratus clouds appeared coming from the east, but soon altered their course and moved in the contrary direction. Soon after 10 a. m. there commenced a succession of light showers and rapid changes in the clouds. It appeared as if the clouds, becoming charged, would move up and precipitate their moisture and then clear away. At 6 p. m. cirrus clouds were observed at a great height, while below them were heavy masses of cumulus clouds. The lower atmosphere at the same time was quite hazy, and on the eastern side of the valley could be seen a long line of fog lying close to the foot of the mountains. No clouds were seen after sunset except lower clouds, they varying in amount from one to four-fourths. Whole amount of rain, .25.

August 22.—To-day's barometric readings were confined between 27.37 and 27.42. Mean barometer, 27.395. The thermometer was stationary at 63°, until after 6 a. m., and then dropped to 62° (the minimum) at 7.14 a. m., advancing rapidly from that time attaining a maximum of 78° at 11 a. m. During the afternoon the column fluctuated between 75° and 67°, and, after sunset, declined gradually to 63° at last observation. Mean temperature, 67°.5. A light variable northeast wind set in at 7.30 a. m., and continued until 3.30 p. m. Dark, heavy stratus clouds covered the entire sky during the early-morning hours. Rain began at 5.45 a. m., and ended at 6.15 a. m. Soon after the rain ceased the stratus clouds broke up, revealing one-fourth cirro cumulus clouds moving from the west. At 8 a. m. the stratus clouds had all disappeared, and two-fourths cumulus and one-fourth cirrus clouds were observed, the cumulus clouds moving rapidly from the northeast, while the cirrus were moving with the same velocity from the north. At 9 a. m. the cumulus clouds had diminished to one-fourth, the cirrus had disappeared, and two-fourths cirro-cumulus occupied their place, while one-fourth stratus clouds were seen below. Soon after this time the stratus and cirro-cumulus clouds became invisible, the cumulus clouds increased and covered the sky at noon. A rain commenced at 12.30 p. m., and continued at intervals until 5.30 p. m. Heavy stratus clouds hung over the station during the rest of the evening. Whole amount of rain, .11.

August 23.—No material change occurred in the readings of the barometer to-day. Mean barometer, 27.434. The temperature ranged at 61° and 63° until after 6 a. m. The column then began to rise and ascended to a maximum of 82° at 1 p. m. A thunder-storm now suddenly arose, and under its influence the column dropped seven degrees, reading 75° at 2 p. m. At 3 p. m. it had risen two degrees, and for the rest of the day declined evenly to a minimum of 57° at midnight. Mean thermometer, 68°.2. No wind to-day except a gentle northeast at 1 p. m., which changed to southeast at 2 p. m., and soon after calmed. The sky remained covered by stratus clouds until about 3.30 a. m., when a dense fog arose and enveloped the station, dissipating about 6.30 a. m. Cirrus and cumulus clouds were visible during the forenoon, moving from the west. At 1 p. m. the cumulus were moving from the northwest, and about one-fourth stratus clouds had formed, and were moving from the northeast. At 1.30 p. m. several loud peals of thunder were heard, and in a few minutes rain descended, lasting only a short time. The cumulus clouds changed direction to the northeast, and the stratus clouds to the southeast, the latter disappearing at 2.30 p. m., and the cumulus again moved from the northwest. At 4 p. m. they had again changed their course to northeast, and soon after no motion was perceptible. About sunset all clouds cleared away. Amount of rain-fall, .02. Worked nearly five hours to-day trying to establish communication with the summit, but could get no response.

August 24.—The barometer advanced slowly until 8.30 a. m., and then declined regularly until 6 p. m., and remained nearly stationary during the rest of the day. Mean barometer, 27.444. The temperature was steady at 55° and 56° until about sunrise, advanced rapidly after that, attaining a maximum of 81° at noon, at which height it remained until after 2 p. m., and then decreased to the minimum, 55°, at midnight. Mean thermometer, 65°.7. Calm all day. The sky remained clear until after 3 a. m., when a fog settled in the valley, covering all objects, but disappeared soon after 4 a. m. A few cumulus clouds were seen during part of the day, having a slow motion from the east and northeast. A haze was visible in the lower atmosphere during part of the afternoon, but vanished about 7 p. m., leaving a beautiful clear sky. Signal communication with the station on the summit was established to-day.

August 25.—The barometer decreased unevenly throughout the day. Mean barometer, 27.363. The thermometer read 55° at 1 a. m., but sank to a minimum of 52° between 3 and 4 a. m., and then began to rise, and went up to a maximum of 82° at 12 o'clock (noon,) and declined unevenly to 65° at 12 p. m. Mean thermometer, 68°.4. The atmosphere has been perfectly calm all day. A fog began to form about 4.30 a. m., developing the station at 5 a. m., but soon dissipated, leaving, at 6 a. m., a line of fog

Digitized by Google

along the river and the upper atmosphere hazy. At 8.30 a. m. cumulus clouds formed, and for the first three hours had a variable direction, sometimes moving from the west, northwest, and northeast, varied in amount from one to three-fourths, and disappearing soon after 6 p. m. Stratus formed about dark, moving steadily from the northwest, rendering the weather cloudy at times, and again clear.

August 26.—The barometer fluctuated considerably to-day, but shows a decrease at last observation. Mean barometer, 27.268. The thermometer has been very unsteady. A temperature of 65° at 1 a. m. fell to a minimum of 62° at 4 a. m., and went up rapidly in the next hour, reading 71° at 5 a. m., continued to rise unevenly until 2 p. m., when it gave a maximum of 83°, that being the highest point reached during the month. After this time the column sank irregularly until 12 p. m. Mean thermometer, 71.8°. Variable gentle winds were felt during the day from southeast, east, and northeast. Stratus clouds formed about 2.30 a. m., moving from some easterly quarter until near 5 a. m., when they changed direction to the west and soon after disappeared. Cumulus clouds were seen at 5 a. m., took up a rapid motion from a point a little north of west, and did not disappear until after 7 p. m. About one-fourth cirrus clouds were visible during the day, being greatly elevated. Stratus clouds formed again at 6 p. m., increased rapidly and covered the entire sky soon after 7 p. m., assuming a threatening appearance. Peal after peal of thunder was heard about 7.20 p. m., and shortly after rain descended, lasting over a half hour. Stratus clouds were visible during the rest of the evening. Total rain-fall, .14.

August 27.—The barometer showed a tendency to fall until about 4 a. m., when it began to rise, continuing until 11 a. m., reading at that time 27.29; for the next two hours it was steady, and then dropped .04 for the 2 p. m. observation; remained at that height until after sunset, and then began to increase and continued at last observation. Mean barometer, 27.262. The thermometer stood at the minimum, 62°, at 1 a. m. varied between that height and 63° until 6 a. m.; the column then began to expand and rose to a maximum of 81° at 1 and 2 p. m. At 3 p. m. it had began to contract and continued unevenly to a temperature of 66° at midnight. Mean thermometer, 70°.9. Calm until 6.30 a. m.; a light east wind was then noticed, but it died away soon after 2 p. m., the atmosphere remaining tranquil the rest of the day. Stratus clouds increased and covered the sky at 2 a. m., but moved off shortly after 4 a. m., leaving a few cumulus and cirrus clouds, the former moving from the west and the latter from the northwest. A fog was also observed hanging over the river, but was soon dissipated by the heat of the sun. The upper clouds were visible until after 5 p. m., when they became hidden by stratus clouds which began to form shortly after 3 p. m., and grew heavy and threatening during the evening. A heavy rain began at 10.37 p. m. and ended at 11.15 p. m., being the first rain we have had for twenty-five hours. Rain-fall, .17.

August 28.—The barometer rose steadily from 27.31 at 1 a. m. to 27.41 at 10 a. m.; remained at that height until 1 p. m., and sank to 27.37 at 3 p. m.; commenced to rise again at 4.30 p. m., and advanced to 27.44 at midnight. Mean barometer, 27.381. The extreme range of the thermometer to-day was only seven degrees. The column was steady at 65° and 64° until 10 a. m., advanced one degree for the 11 a. m., and fell off for the 12 m. Attained a maximum of 69° at 2 p. m., and contracted to 63° at 7 p. m., held that point until 11 p. m., and then dropped to a minimum of 62° at 12 p. m. Mean thermometer, 65°.4. Light winds, varying from east to south, were felt for a few minutes at different times of the day. The sky has been completely covered with dark, heavy clouds all day. A few light showers fell, amounting in all to .06 inch.

August 29.—The barometer continued to ascend to-day, but its course is marked by fluctuations, and the increase is small. Mean barometer, 27.478. The thermometer read 62° at the first observation, and sank to a minimum of 61° at 2 a. m., remained at that height until after 6 a. m., and then began to rise, going up to a maximum of 72° at 11 a. m., dropped one degree at noon, and reached the maximum again at 2 p. m.; contracted after this to 62° at midnight. Mean thermometer, 65°.7. Calm until 10.30 a. m., when a just perceptible east wind was felt, but which calmed at noon. About 12.30 p. m. this wind was again felt, but changed to southeast at 2.45 p. m., and calmed at 5.30 p. m., remaining so for the rest of the day. The sky remained covered by stratus clouds until near 10 a. m., when they cleared away revealing three-fourths cumulus clouds moving from the north. They soon changed their direction to west, and shortly after 12 m. became hidden by stratus clouds, which were moving from the southeast, and partly cleared away after 8 p. m.

August 30.—The barometer stood at 27.50 until after 4 a. m. and then rose to 27.55 at 9 a. m., decreased slowly to 27.46 at 4 p. m., and showed a slight increase at 12 p. m. Mean barometer, 27.500. The thermometer was steady at 62° until after 6 a. m., advanced and attained a maximum of 77° at 11 a. m., and decreased slowly to a minimum of 56° at midnight. Mean thermometer, 66°.6. A light northwest wind was stirring at noon, but soon died away. The sky was about half-covered with stratus clouds at 1 a. m., which increased to four-fourths at next observation, and did not entirely disappear until after 8 a. m. Cumulus clouds formed after 6 a. m., having a rapid motion

Digitized by Google

from the west, varied in amount from one to four-fourths, and disappeared after 8 p. m. The lower atmosphere grew hazy in the afternoon.

August 31.—The barometer fluctuated between 27.49 and 27.47 until 3 a. m. and then dropped to 27.44 for the 4 a. m., and oscillated between that height and 27.37 for the rest of the day. Mean barometer 27.421. The thermometer exhibited a minimum of 56° for the first four hours and then advanced regularly to a maximum of 81° at 2 and 3 p. m., declining to the minimum again at last observation. Mean thermometer, 66°.7. Calm until 10 a. m., a light northeast wind then sprung up and continued until after 4 p. m., blew for a short time from the southeast about 5 p. m., and then calmed. Stratus clouds formed and covered the sky at 2 a. m.; sank down into the valley, forming fog, at 5 a. m.; cleared off about 8 a. m., showing cirrus and cumulus clouds, the former moving from the northeast and the latter from the west. Cirrus clouds disappeared about 10.30 a. m. and the cumulus clouds about sunset.

September 1.—The barometer has been constantly in motion during the past twenty-four hours; the midnight reading shows a decrease of .03. Mean barometer, 27.346. The thermometer read 55° at the first observation; ascended to 56° at 3 a. m., and sank to a minimum of 54° at 5 a. m.; remained at this point until after 6 a. m., and then advanced rapidly to a maximum of 83° at 1 p. m., and declined unevenly to 62° at midnight. Mean thermometer, 67°.7. Calm until 10.30 a. m. A light south wind then sprung up, changing to northwest at 11.45 a. m. and died away after 1 p. m., remaining calm the rest of the day. Stratus clouds formed and covered the sky at 3 a. m., but soon broke up and disappeared. A fog formed on the river, spread over the adjacent country, and covered objects at 5 a. m., and dissipated between 7 and 8 a. m. Cumulus, cirrus, cirro-cumulus, and cirro-stratus clouds were observed at different times of the day, but all disappeared about 11.30 p. m.

September 2.—The barometer fluctuated some to-day, but shows an increase of .04 at last observation. Mean barometer, 27.342. The thermometer fell from 60° at 1 a. m. to a minimum of 56° at 3 a. m.; attained a maximum of 83° at noon, which point it held until after 2 p. m., and then declined to 61° at midnight. Mean thermometer 68°.7. No wind was perceptible until noon. A gentle east wind then set in, but soon changed to north and then calmed. Light west to southwest winds were observed at different times during the balance of the day. A haze was visible at first observation, but a fog arose and soon hid everything; cleared off during the morning, revealing cirrus clouds, varying in amount from one to three-fourths. Cumulus clouds formed about noon, having a slow motion from the west, which changed to north at 1 p. m. A light shower of rain fell between 3.25 and 4 p. m., the amount not being sufficient to measure. About 5 p. m. the cumulus clouds were again moving from the west; stratus clouds began forming and assumed a threatening appearance at 7 p. m.; at half-past seven, successive flashes of lightning were seen, accompanied by terrific thunder. This thunder-storm drew near the station, and at last appeared to be centered directly over it. Flashes of lightning now followed each other in rapid succession, their thunder causing the building to shake violently. At 7.45 p. m. the rain descended in torrents. The barometer rose rapidly, and soon the storm passed over. The clouds broke up, and part moved off, leaving the sky half covered. Fair weather continued until after 11 p. m., and then the stratus clouds increased and covered the entire sky. Whole amount of rain collected, .50.

September 3.—The barometer remained steady at 27.37 for the first two observations, sank .01 at 3 a. m., and advanced to 27.40, at 6 a. m; exhibited this reading until after 11 a. m.; declined regularly to 27.31 at 4.14 p. m., and fluctuated between this height and 27.34 the rest of the day. Mean barometer, 27.361. The thermometer decreased from 60° at the commencement of the day to a minimum of 56° at 5 and 6 a. m. The column then began to rise and went up to a maximum of 80° at noon. Kept this point for four hours and then decreased evenly to 62° at 12 p. m. Mean thermometer 68°. A light southwest wind sprung up at 9.30 a. m., veered by the south point to northeast at 11 a. m. and backed to south at noon, but soon settled steady from the southwest, in which direction it remained until after 4 p. m. and then calmed. Foggy, fair, and clear weather is alternately reported until after 8 a. m. Cumulus clouds then appeared moving slowly from the southwest, but became hidden by stratus clouds at 5 p. m. Stratus clouds broke up at 7.30 p. m., exhibiting a few cirrus and cumulus clouds, but spread and covered the sky again at midnight.

September 4.—The barometer fluctuated to-day between 27.27 and 27.37. Mean barometer 27.320. The thermometer was steady at 61° and a minimum of 60° until 7.14 a. m., increased to a maximum of 78° at 3 p. m., and declined gradually to 66° at last observation. Mean thermometer, 68°.6. A light northeast breeze set in about 1 p. m., lasted until after 5 p. m., and then changed to south; calmed at 9 p. m. Stratus clouds, varying from one to three-fourths, were visible until 4 a. m. Cumulus and cirrus clouds appeared then, but became hidden by stratus clouds at 9 a. m. A light rain fell between 10.18 and 10.55 a. m., amounting to .03. Stratus, cumulus, and cirrus clouds were observed until 8.30 p. m. when the two first disappeared, leaving a few cirrus clouds.

Digitized by Google

September 5.—The barometer stood 27.32 at the three first observations, the pressure then increased, and the column advanced to 27.40 at 11 a. m., began to sink soon after, and fell to 27.34 at 3 p. m.; began to rise again and went up to 27.40 at midnight. Mean barometer, 27.369. The thermometer has stood high all day; read 65° at 1 a. m., advanced to 73° at 3 a. m., and sank to 70° at 5 a. m.; began to rise soon after, and attained a maximum of 81° at 2 p. m., and decreased slowly to a minimum of 61° at midnight. Mean thermometer, 72°.0. A gentle north wind set in about 1.30 a. m., increased to fresh at 3 a. m., changed to northeast by 4 a. m., and calmed at 8.30 a. m. A few southeast and northeast motions were perceptible during the afternoon; the remainder of the day was calm. Cumulus and cirrus clouds have been prevalent to-day; the cumulus clouds moving from the west and southwest and the cirrus clouds northwest and south.

INSTRUMENTS, ETC.

In placing the maximum thermometer in position, the bulb accidentally became broken, rendering it useless. The remainder of the instruments are in good condition and have worked well.

D. H. SACKETT,
Observer Signal-Service, U. S. A.

PAPER 18.

INSTRUCTIONS FOR MAKING AND REPORTING TELEGRAPHIC RIVER OBSERVATIONS FOR THE SIGNAL-SERVICE, UNITED STATES ARMY.

WAR DEPARTMENT, OFFICE OF THE CHIEF SIGNAL-OFFICER,
DIVISION OF TELEGRAMS AND REPORTS FOR THE
BENEFIT OF COMMERCE AND AGRICULTURE.
Washington, D. C., April 10, 1873.

1. All measurements at each station will be made from the bench-mark or water-level in common use by river-men at that station, and the depth of water from the low of the river to this level, at the point where the gauge in use is located, will be reported to this office at the time of sending in the first mail reports.

2. The gauge used will be put up by the observer at each station at the expense of this office, and will be made of pine or oak timber, two inches thick by ten inches in width, and of sufficient length to cover the full range of the river between extreme low-water and high-water marks. This timber will be placed edgewise and firmly imbedded in the earth, leaving one and a half inches of its width exposed above the level of the ground. The upper edge will be planed smooth, and carefully graduated in feet and inches, *after being placed in position*, taking the established bench-mark or level referred to in Par. 1 as the zero of the scale, and numbering the feet and inches both above and below that point, unless it is at extreme low-water mark, in which case the numbers will all be above the zero of the scale. [Figures 1 and 2.] Especial pains will be taken in graduating the gauge to see that the distances marked off upon it for each foot and its subdivisions will correspond exactly to the vertical foot and subdivisions of which they are the measure. This can be readily done by means of an ordinary spirit-level, a straight-edge on which to place the level, and a graduated rule fixed vertically, from which to take the measurement.

3. Observations will be made daily from May 1 to July 31 and October 1 to November 30 of each year, and at such intermediate times as may be desired by the Chief Signal-Officer, or rendered necessary by any sudden or unexpected change in the condition of the river.

4. Whenever the rise or fall of water is gradual, one observation per day will be made at 3 p. m., local time, during the periods named above. When the change is sudden and unusual in its character, reports will be made every three hours during such change until the river resumes its normal condition.

5. Observations will be made on Sundays at the regular hours, and delivered punctually at the telegraph-office, as on other days of the week.

6. All regular reports will be sent in the cipher accompanying these instructions and signed "Observer," only. The *name* of the observer will not be given. They will consist of five words each, (beside the address and signature,) arranged in the following order:

1. Name of station.
2. Date and time of report.

Digitized by Google

of weather and direction of wind.
h of water in feet.
h of water in inches.
th word will show the distance in feet above or below the bench-mark, h word the odd inches, when there are any. If the depth can be expressed ie, the word "naught" will be sent in the fifth space. When the river is me of report, observers will use the cipher-words in the column headed l those in the column headed "Fall" when it is falling.

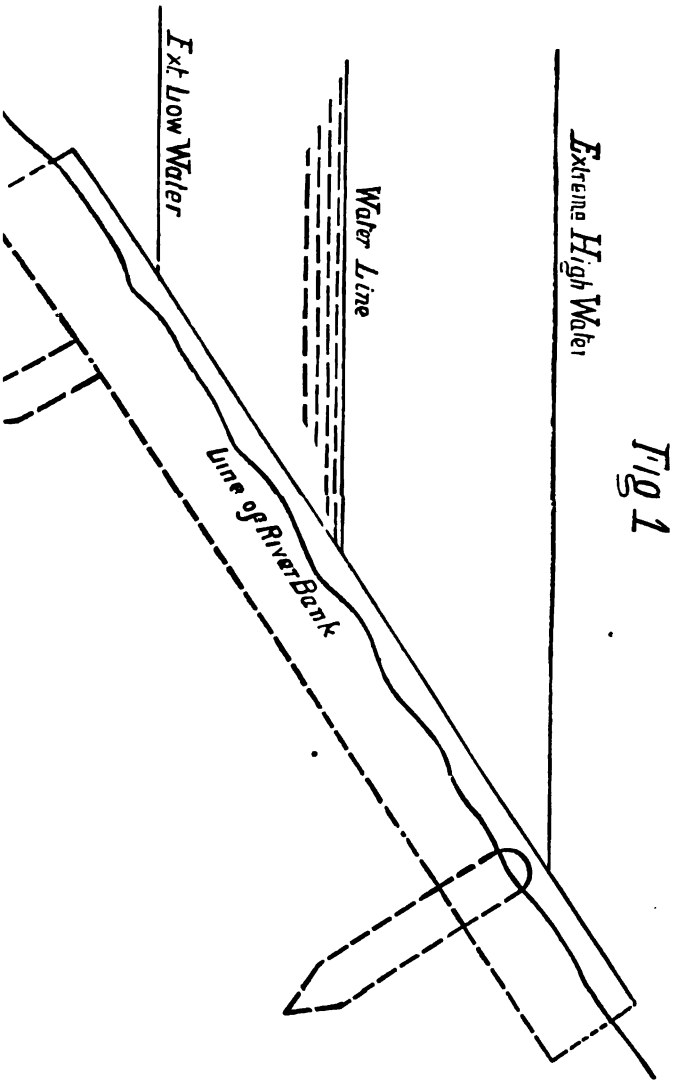

Fig 1

eports will be written in duplicate on Form 1, and one copy filed, properly and signed, at the telegraph-office within thirty minutes after the observa- ıde. The report from ——— will be sent to the observer-sergeant at ———. ıed copy of each report made during any one day will be mailed on the morn- succeeding day to the "Chief Signal-Officer, Washington, D. C." duplicates (Form 1) must be properly dated, timed, and signed, as indicated forms, and must also show upon their face the time at which they were filed egraph-office.

Digitized by Google

9. A weekly report (on Form 27) will be made to this office, showing the number of reports sent during each day of the week; the line by which they were sent; time of filing in telegraph-office; and such other data as may be indicated by the heads of the different columns.

10. All necessary blanks, forms, stationery, &c., will be furnished by this office, and will not be purchased by observers without special authority from the Chief Signal-Officer. Timely requisition will be made upon this office for additional blanks and stationery whenever necessary.

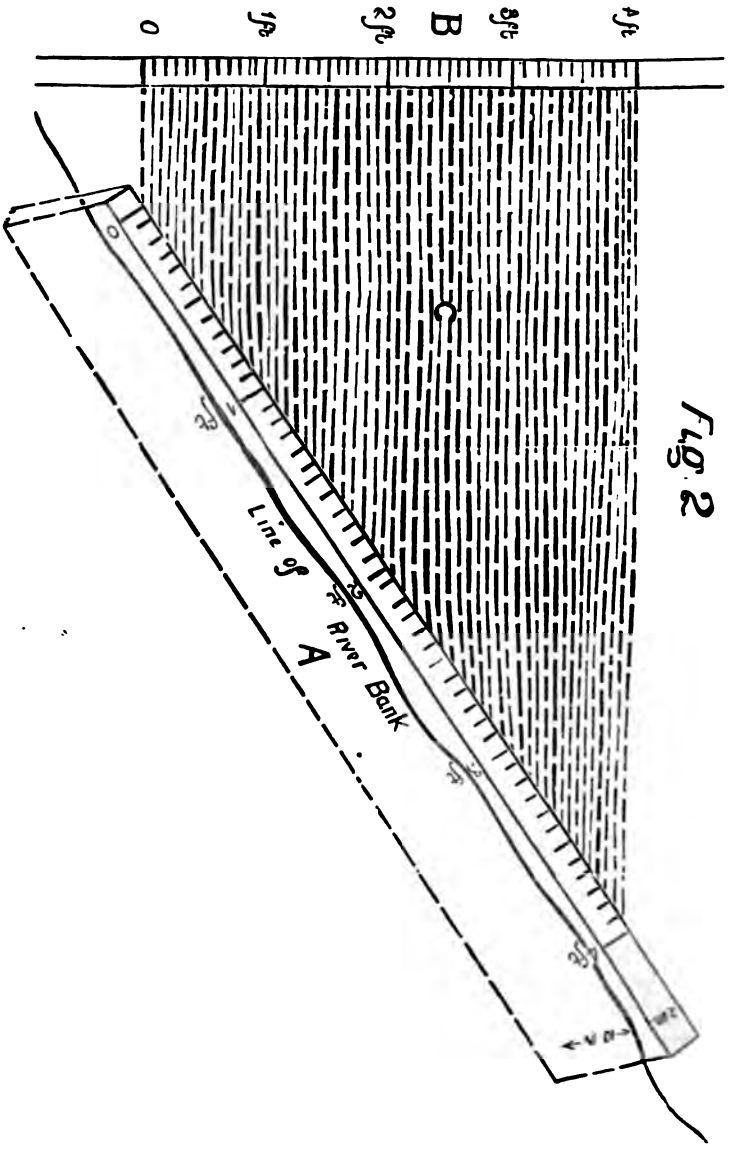

Fig. 2

11. All bills for services or for material furnished should be rendered monthly, and will be settled by the property and disbursing officer of the Signal-Office as soon after their receipt as the necessary vouchers can be signed. The bill for construction of gauge will be settled promptly upon its receipt at this office. Observers will not [illegible]

ms or reports on official business, as settlement will be made by the office
legraph company direct.
vers will arrange, as far as practicable, to have some competent, reliable
ake reports in case of their sickness or unavoidable absence; and, when
, will see that the person so employed is properly instructed in his duties.
l telegraphic reports will be made to this office of the formation or break-
ce-gorges or other obstructions in the river, and of the presence of float-
mber, when of sufficient extent to render navigation unsafe, stating, in
ds as possible, the location and extent of the gorge, break, or obstruction
ance.
expected that all observers will make their obervations and reports *accu-*
promptly, bearing constantly in mind the fact that their usefulness, when
this office, depends wholly upon these two conditions.
hief Signal-Officer reserves to himself the right of withholding payment
server who shall neglect to make his reports accurately and promptly.
ever necessary, reports from adjoining stations will be sent to observers,
given by them to the press, and also posted in such public places as are
nted by river-men and merchants interested in the condition of the river.
l communications by mail, addressed "Chief Signal-Officer of the Army,
n, D. C.," go free of postage until June 30, 1873, after which they must be
tamps for this purpose will be furnished from the Signal-Office.

FOR TRANSMISSION OF TELEGRAPHIC RIVER OBSERVATIONS FOR THE SIGNAL-SERVICE, UNITED STATES ARMY.

INSTRUCTIONS FOR USING THE CIPHER.

report will consist of *five* words besides the address and signature. In the
of the form used the *name* of the station from which the report is made will
; in the second space, the word for *date* and *time* of report; in the third space,
state of weather and *direction of wind*; in the fourth space, the *depth* of water
in the fifth space the *depth in inches* in excess of the feet. The cipher-words
ll cases be written plainly and correctly.

EXAMPLE.

(Form 1.)

WAR DEPARTMENT, SIGNAL-SERVICE UNITED STATES ARMY,
DIVISION OF TELEGRAMS AND REPORTS FOR THE
BENEFIT OF COMMERCE AND AGRICULTURE.

Report of observation taken at Hermann on April 1, at 6 p. m.

rver-Sergeant, Saint Louis.				
nn.	Gab.	Lomond.	Harden.	Often.
				Observer.

to operator at 6.20 p. m.
Operators will send only the matter inside the heavy lines.

Translation.

	Name of station	Hermann.
	Date of report	First day of the month.
	Time of report	6 o'clock p. m.
	State of weather	Heavy rain.
	Direction of wind	Northwest.
	Height of water above bench-mark	12 feet 5 inches.

River rising.

her-words to be used when the water is either *above* or *below* the bench-
l be found on page 956. When the water is *rising*, the words will be
m the left-hand columns; when it is *falling*, from the right-hand columns.

APPENDIX.

The following table of elevations is furnished for the information of all observers. Any errors in the figures and any changes in location of office or elevation of barometer since date given opposite each station will be promptly reported to this office. If no changes have taken place since the date named in the following table, the elevation given will be used for correcting all barometrical observations.

Station and date of last reported change.	Elevation of barometer above ground at office.	Elevation of ground at office above bench-mark.	Bench-mark.	Elevation of bench-mark above mean sea-level.	Total elevation to be corrected for.

NOTE.—By "mean sea-level" is meant the mean of the "mean low tide" and "mean high tide" given by the Coast Survey Observations.

The following table is furnished for the information and guidance of all concerned. The regular hours for taking the telegraphic observations are 7.35 a. m., 4.35 p. m., and 11 p. m., Washington mean time.

At stations west of Washington the figures given in the table for each station will be subtracted from the above hours, and the remainder will show the proper local time for the observations.

At stations east of Washington the figures in the table will be added to these hours to obtain the proper local time. Any discrepancies discovered between the figures given here and the local time in use at each station will be promptly reported to this office.

Table showing the difference between local time and Washington mean time at the signal-stations named:

PAPER 19.

The following statement showing the location of the bench-marks from which the rise and fall of the western rivers is measured for the river-reports of this office is published for the information of all concerned.

BROWNSVILLE, PA.

The zero point on gauge is the depth of water in the channel on June 5, 1873, which was 5 feet.

BRUNSWICK, MO.

The zero of scale is the low-water mark at this point.

CAIRO, ILL.

The zero of gauge is placed at extreme low water of December, 1871. Extreme high water occurred in 1867, when it reached the top of the levee, which is 53 feet above low-water mark.

The bench-mark is the top of the levee.

CINCINNATI, OHIO.

The bench-mark is 20 inches above the bottom of the river—extreme low water. The high-water mark is a point 65 feet 5 inches above the bench-mark.

Extreme high water occurred March 7, 1865, and extreme low water September 13, 1858.

CONFLUENCE, PA.

Depth of river May 19, 1873, 30 inches.
Depth of river at low-water mark, 12 inches.
Zero of gauge above low-water mark, 18 inches.

Digitized by Google

DAVENPORT, IOWA.

The gauge was constructed by Colonel Macomb, United States Engineers, on the pivot on draw-bridge pier of the Government bridge, between Davenport and Rock Island. It is in the Davenport channel, and is cut in the stone-work and painted in black and graduated into feet and tenths. Its zero point is the low water of 1863, the lowest water known.

EVANSVILLE, IND.

The zero of gauge is placed at low-water mark of 1867, being 6 feet above the bed of river. A survey made at 3 p. m., April 19, 1873, gave depth of water above low-water mark (1867) 25 feet 4 inches.

FORT BENTON, M. T.

The bench-marks are two iron bars let into river-bank, one at the highest water mark of 1872, the other 19 inches above the lowest water of 1872.

The measurements give the depth of water on the bar in front of the town. The depth of water over the bar at high water is 8 feet 10 inches—at low water not over 18 inches.

NOTE.—Observer ordered by Chief Signal-Officer to use low-water mark as the zero of river-reports instead of bench-mark.

FORT SULLY, D. T.

The means of measurement are two (2) poles planed square, 6 feet 6 inches long, and accurately graduated. They have to be changed daily "to accommodate" the river. The actual depth of water is reported.

FREEPORT, PA.

The bench-mark is 4 feet 6 inches above extreme low-water mark.

HERMANN, MO.

The gauge rests upon the bed of the river and indicates actual depth of water. Depth of water April 24, 1873, at 3 p. m., 12 feet.

JEFFERSON CITY, MO.

Reports are made from low water of 1867 and high water of 1844, the river in 1844 being 31 feet higher than low water of 1867.

Depth of water May 12, 1873, at 3 p. m., 10 feet 10 inches above low-water mark.

KANSAS CITY, MO.

Low-water mark, as established by the chief engineer Missouri River Bridge Company, was in 1867, it being then lower than at any time during which a record was kept. In 1872 it was down to within 7 inches of the mark of 1867. High-water mark, 1844.

KEOKUK, IOWA.

The bench-mark is at the northeast corner of Old Pilot's Indicator, 1,400 feet above the bridge. The height above low-water mark is 24.183 feet, and above high water 8.95 feet. The measurement is not made from the bed of river.

Depth of water in channel at extreme low water, 4 feet 6 inches, and at extreme high water, 24 feet 9 inches to 25 feet 4 inches.

LEAVENWORTH, KANS.

The zero of gauge is placed to correspond with low water in Missouri River. The bench-mark is low water. When the gauge reads 4 feet above zero, there is about 5 feet of water in the river. The bottom of the river changes with the rise and fall of the river.

LEXINGTON, MO.

The zero of gauge is at low-water mark of 1861, being 10 feet 8 inches above the bed of the river. Depth of water in river opposite to gauge, according to measurement made May 15, 1873, was 17 feet 10 inches from bed of the river.

LITTLE ROCK, ARK.

The bottom of gauge is marked 2 feet, and when the water is at that mark there is 2 feet of water in the river. All river-men go by this mark, and the same is reported to the packet company at Memphis and Saint Louis.

Digitized by Google

LOUISVILLE, KY.

The zero is the sill of the lock of the Louisville and Portland Canal. The bench-mark is the door-sill of house corner of Tenth and Water streets, and is 28.1 feet above zero. Extreme high water of February 21, 1832, is 41.8 feet above zero. The depth of water is taken from a gauge at the foot of Tenth street, and is used by all river-men. There is no mark that gives the depth of channel.

MARIETTA, OHIO.

Depth of water at time of first report, April 17, 1873, at 3 p. m., was 13 feet 10 inches in the channel.

MEMPHIS, TENN.

The bench-mark on Exchange Building is 148.789 feet above city-level from the bed of the river. High water from the same datum, 100.8 feet in 1867. Low water from same datum, 65.05, December 25, 1872. Water about 70 feet deep in front of city at low water. (?)

NASHVILLE, TENN.

The bench-mark is 62.75 feet above the zero of gauge. The zero corresponds to extreme low water. Bench-mark 23.25 feet above highest water since Nashville has been a signal-station. No definite data as to year of high and low-water marks can be obtained.

MORGANTOWN, WEST VA.

The gauge rests upon the bed of the river, and reports indicate the exact depth of water in the channel.

NEW ORLEANS, LA.

The bench-mark is high-water mark of 1871, (and is marked on the city tide-gauge at which the zero of gauge (from which all river measurements are made) is placed. From this point to the bottom of the river is approximately 178 feet. The zero is 1[illegible] feet above sea-level and 10.5 feet below the city datum-line.

OMAHA, NEBR.

The gauge is attached to a pier of the Union Pacific Railroad bridge, and its zero is the low-water mark of 1867. The high-water mark of the same year is 19 feet above zero of gauge.

PADUCAH, KY.

Depth of water in channel of the river is 59 feet—May 23, 1873. Depth of water below zero of gauge, 56 feet. Low-water mark—depth of channel in 1854—8 feet [illegible] inches.

PITTSBURGH, PA.

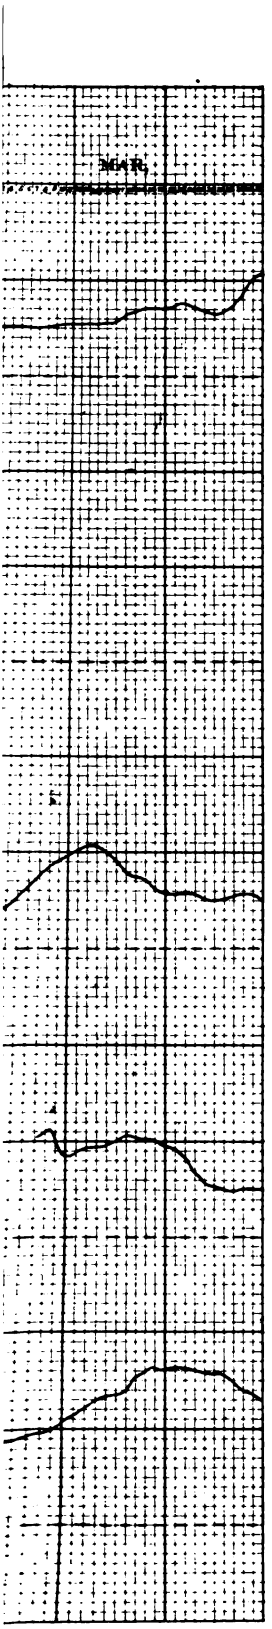
The gauge measures the depth of water in the channel. The greatest depth that can be measured by it is 35 feet; the least is two feet. When the water falls below 2 feet another gauge is used. The lowest water-mark known is 9 inches in the channel; the highest water has never reached the top of gauge.

PLATTSMOUTH, NEBR.

There is no fixed bench-mark at this place. Depth of water at 3 p. m., April 19, 1873 3 feet 3 inches.

SHREVEPORT, LA.

The bench-mark is on Commerce street, adjoining the "Transfer Grounds" of the Texas Pacific Railroad. The lowest water-mark, 1872, the reference point in reporting depth of river, is in the bed of river, and 40 feet below high water of 1849, and 25 feet above bottom of river. From bottom of river to high-water mark of 1849 is 65 feet.



SAINT JOSEPH, MO.

The zero of guage is at low-water mark of 1871. Depth of water from the river-bed to the zero of guage is 8 feet. The navigable depth of water in the channel is 4 feet. Usual depth on bars and shoals during low water is about 3 or 4 feet. From bed-rock to zero of the gauge at Saint Joe, as per the bridge measurement, is 50 feet.

SAINT LOUIS, MO.

The bench-mark is extreme low water of 1863, and high water of 1844. Range of gauge between these two points is 41.39 feet. The gauge has stone foundation and is located at the southeast corner of the Saint Louis elevator building.

SAINT PAUL, MINN.

The bench-mark is at the pier of the bridge and is marked at extreme low water of 64. The daily report of river is the depth of water above that mark. The depth of ıter in the channel at extreme low water is 1 foot 11 inches. There is no high-water ırk of any reliability.

VICKSBURGH, MISS.

The bench-mark is attached to one of the posts which supports the elevator located the levee between Crawford and South streets, and is low-water mark of 1871. om it all measurements are made and the zero of the gauge is adjusted to it. Ex- ıme high-water mark of 1862 is 52.9 feet above the bench-mark. The river-bed is 50 ıt 6 inches below, making the depth of water in the channel, when the river is at gh-water mark, 103 feet 3 inches.

YANKTON, D. T.

The bed of river is the zero point of the gauge, and the actual depth of water in the annel is therefore reported.

LA CROSSE, WIS.

The zero of gauge is low-water mark of October 1, 1871, and is 2 feet 2½ inches above e bed of the river. The gauge is attached to one of the piles of the bridge leading North La Crosse.

OIL CITY, PA.

The "bench" is low water of some year when there was 12 inches of water in the annel. The zero of gauge corresponds with this point.

BOONEVILLE, MO.

Measurements are made from the bed of the river. Depth at high water of 1872, feet; depth at low water, 2 feet 6 inches.

NEW GENEVA, PA.

The bench-mark (the zero of gauge) indicates 4 feet of water in the channel. The ghest water occurred in April, 1852, when there was 40 feet of water in the channel.

LE CLAIRE, IOWA.

The gauge used here was built by the Pilot Association in 1865; its bottom (zero int) is at extreme low-water mark of 1864, which indicates 21 inches of water on e rapids.

DUBUQUE, IOWA.

The gauge used at this station is located at the foot of Seventh street. Its zero int is low-water mark of October, 1864, which is 21 feet 10 inches below the high- ıter mark of April 22, 1870. The average depth of water in the channel is 18 feet low the low-water mark of 1864.

PAPER 20.

REPORT OF INSTRUMENT-ROOM.

Number of instruments compared from October 1, 1872, to September 30, 1873.

ırometers	122
ıermometers	142
ygrometers	42
ygrodeiks	12
aximum thermometers	39
inimum thermometers	39
ıemometers	77
ıeroid barometers	6

These comparisons were carefully made by First Lieut. H. H. C. Dunwoody, acting gnal-officer and assistant, and Sergts. George C. Schaeffer and D. C. Ralston, Signal- rvice, United States Army.

Digitized by Google

Corrections for instrumental error of the several barometers have been computed uniformly from a series of fifty readings compared with a similar series of readings of the standard barometer. When the result of these readings gave an error of more than one-tenth of one inch, the instrument was regarded as unfit for use.

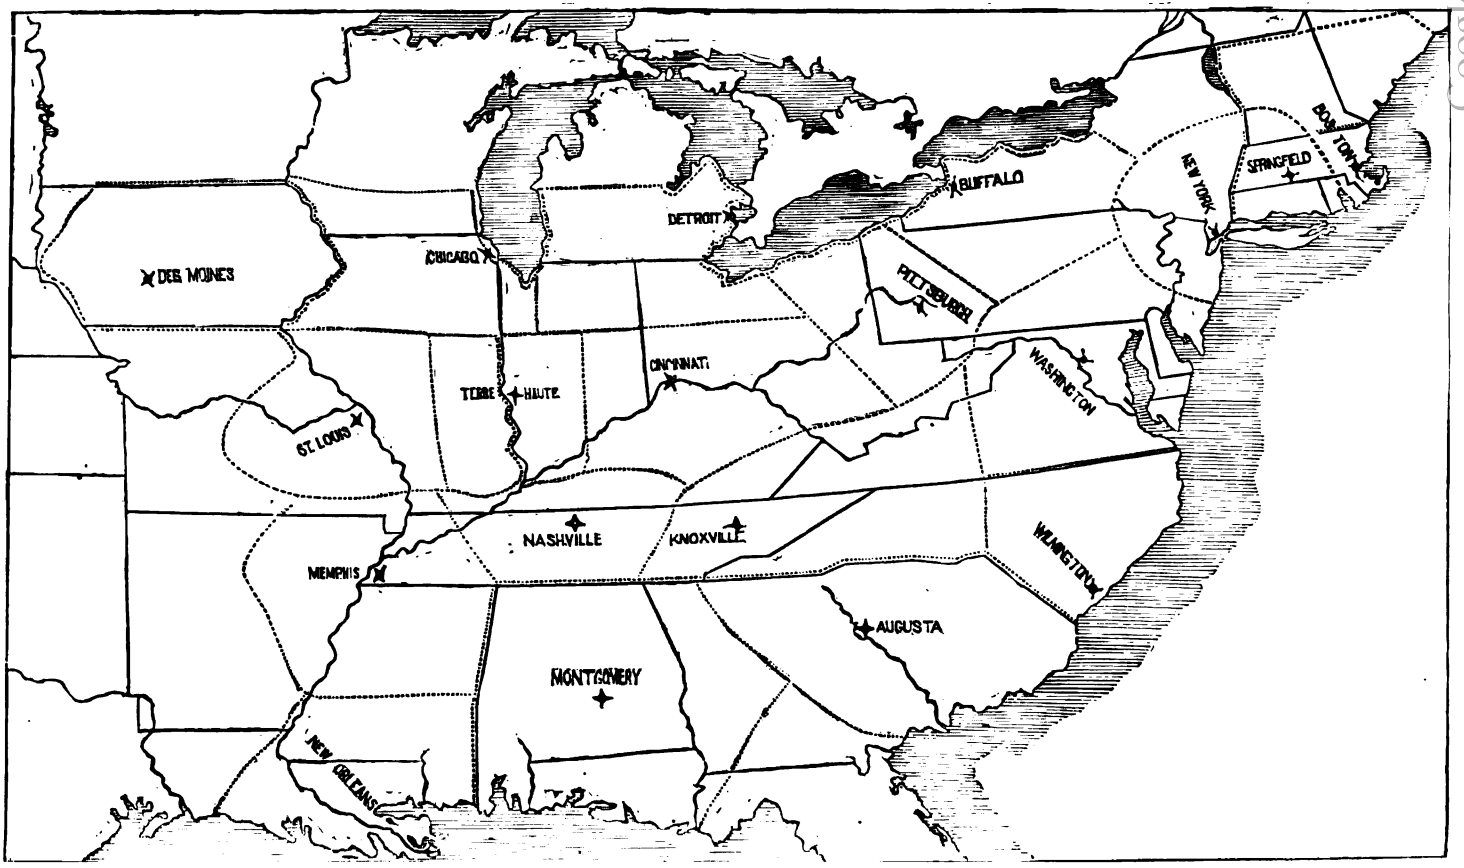
The thermometers have been compared with the standard at temperature varying from that of melting ice to 130° Fahrenheit, the lower temperature being produced by broken ice. For the indication of the higher temperature, the bulbs of the thermometers were immersed in heated water.

In these comparisons a variation of one degree from the standard rendered the instrument unfit for use.

The following-named self-recording instruments have been in practical use in the instrument-room during the past year, and the records filed:

Hough's electrical printing barometer.
Hough's electrical recording barometer.
Wild's mechanical barometer.
Peelor's mechanical barometer.
Beck's aneroid barometer.
Photographic barometer.
Clum's aelleograph.
Hough's electrical meteorograph, (barometer, thermometer, and hygrometer.)
Wild's hygrometer and thermometer.
Photographic thermometers.
Gibbon's electrical recording anemometer.
Gibbon's electrical recording anemometer and anemoscope.
Beck's mechanical recording anemometer and anemoscope.
Wild's mechanical anemometer, anemoscope, and rain-gauge.
Draper's mechanical anemometer for velocity.
Draper's mechanical anemometer for pressure.
Draper's mechanical anemoscope.
Draper's mechanical rain-gauge.
Beckley's mechanical rain-gauge.
Gibbon's electrical recording tide-gauge.
Dunwoody's electrical tide-gauge.

Two glass cases, in which are represented the different atmospheric phenomena, have been constructed by Private P. A. Monnet, Signal-Service, United States Army. Both cases contain specimens of clouds arranged in the style of a panorama. The smaller case gives only the principal outlines of the objects, and may be considered as a short synopsis of that branch of meteorology. The larger case is more particularly adapted for nephelegraphic studies, each type of cloud being therein exhibited in its most essential character, and surrounded with its principal derivatives. The broader forms and those above them are separate types; whereas the two lower strata, being the terrestrial range, correspond to combined meteors, viz: aqueous, aerial, and luminous. Some phenomena of the last class, like haze, auroras, coloration at sunrise and sunset, can be produced at pleasure by optical attachments external to the case. The chief object aimed at in both styles of representation is to trace the effects of atmospheric agencies on aqueous vapor.



PAPER 21.

CORRESPONDENCE IN REFERENCE TO THE CO-OPERATION OF THE POST-OFFICE AND WAR DEPARTMENTS IN THE DISTRIBUTION OF WEATHER-REPORTS.

WAR DEPARTMENT, OFFICE OF THE CHIEF SIGNAL-OFFICER,
DIVISION OF TELEGRAMS AND REPORTS
FOR THE BENEFIT OF COMMERCE AND AGRICULTURE,
Washington, D. C., December 7, 1872

SIR: I have the honor to request that instructions may issue to the postmasters at the post-offices named in the accompanying list A, herewith, to display daily and instantly upon their receipt by mail, upon bulletin-boards, which will be furnished (if permitted by the Postmaster-General) from this office, the reports as to the probable condition of the weather in the sections in which these offices are located, which this office will furnish by mail daily in printed form, and addressed to the postmasters named respectively. Under section 6 of the act of Congress entitled "An act to revise, consolidate, and amend the statutes relating to the Post-Office Department," approved

June 8, 1872, the request of the honorable Postmaster-General that this publication be made by the postmasters, or others in his service, as being for the public good, would clearly have the effect of an order; but should there be question on this point, there can be none that most of the postmasters interested would gladly perform the duty as for the public good, and one reflecting credit upon the Department in which they serve.

To the Postmaster-General himself, whose good-will to this Bureau has been so often and with such benefit to the Department evidenced, the Chief Signal-Officer does not feel it necessary to urge at length reasons for requesting his valuable co-operation. It is sufficient to say that the plan suggested seems to offer a more immediate and extensive method of reaching the whole interior and agricultural populations of the United States, with information in which each citizen has an interest, than any hitherto put in use in any country in the world.

Attention is respectfully invited to the accompanying memorandum of the plan of distribution.

I am, sir, very respectfully, your obedient servant,

ALBERT J. MYER,
Brigadier-General and Chief Signal-Officer of the Army.

The Hon. POSTMASTER-GENERAL.
(Through the Hon. Secretary of War.)

PLAN OF WORK.

It is proposed to divide the territory east of the Mississippi River into districts of bout two hundred miles in diameter, each district having a distributing point at or ear its center, from which two copies of the reports will be mailed daily to all postffices accessible by rail or mail-coach by 6 p. m. each day. At each office the postaster is to post one copy of each report, as soon as received, in a frame to be furnished by the Signal-Office, which frame will be put up in a conspicuous part of the ffice, where it can be seen and the bulletins read by the public without difficulty.

The second copy is intended for the personal use of the postmaster, and may be disosed of in the manner he thinks best calculated to diffuse the information it contains. he chart herewith illustrates the proposed form of districting.

MEMORANDUM.

The extent of the co-operation required of the Post-Office Department is the transission daily by mail of one additional letter to each post-office named in the schedules, id the putting up daily at such offices one copy of the bulletins furnished by the gnal-Office.

WAR DEPARTMENT,
Washington City, December 9, 1872.

SIR: I have the honor to inclose herewith a communication from the Chief Sigl-Officer of the Army, relative to distribution of the daily weather-reports, and to quest the co-operation of your Department in the mode indicated by him, if content with your views. The subject is one of public interest, and the plan appears pable of effecting a public good.

Very respectfully, your obedient servant,

WM. W. BELKNAP,
Secretary of War.

The Hon. POSTMASTER-GENERAL.

POST-OFFICE DEPARTMENT,
Washington, D. C., December 11, 1872.

SIR: I have the honor to acknowledge the receipt of your letter of the 9th instant losing a communication from the Chief Signal-Officer of the Army, with schedules l plans for the co-operation of the Post-Office and War Departments in distributing daily weather-reports throughout the agricultural districts of the United States essible by rail or mail-coach, by 6 p. m. each day, from certain designated distribng points.

heartily approve of the plan proposed by General Myer for extending to the agritural sections of the country the benefit of the information contained in the daily ather-reports from the Signal-Office, and have issued an order under date of 9th

Digitized by Google

instant, a copy of which is inclosed herewith, instructing all postmasters receiving these reports by mail to post them immediately in the frames supplied for that purpose by the Signal-Office.

Any further assistance that may be desired from this Department will be most cheerfully given.

I am, very respectfully, your obedient servant,

JNO. A. J. CRESWELL,
Postmaster-General.

Hon. WM. W. BELKNAP,
Secretary of War.

POST-OFFICE DEPARTMENT,
Washington, D. C., December 10, 1872.

Arrangements have been made between the Post-Office and War Departments by which one or more of the daily weather-reports issued by the signal-office will be furnished daily to all the post-offices that can be reached from the several points of distribution daily by mail. As these reports are designed for the benefit of the agricultural as well as the commercial interests of the country, the Postmaster-General instructs all postmasters receiving them to post them *immediately* in the frames supplied for this purpose by the signal-office.

PAPER 26.

MONTHLY WEATHER-REVIEW, OCTOBER, 1872.

STORMS.

e progress over the country of thirteen storm-centers has, during the month, been d upon the War Department weather-maps, Signal Service, United States Army. most severe of these storms was that which, from the 21st to the 27th, traveled the Gulf northeastward over the South Atlantic and Middle States, and thence ard over southern New England into the Atlantic, attended throughout its course avy rains and brisk to high winds, increasing at times to gales. These rains particularly heavy in Northeastern Florida and Southeastern Virginia, over 6 s of water falling during the storm at Jacksonville, and nearly 7¼ inches at Nor-

Of the remainder of these disturbances nine pursued an irregular eastward e from the northwest over the lake region into Canada or New York or New Eng- to Brunswick or Nova Scotia; one moved from Texas eastward into the Gulf, e it disappeared; one nearly northward from off Cape Cod across Maine to New swick, and one from Kansas and Nebraska eastward over the Ohio Valley to Vir-

Digitized by Google

RAIN-FALL.

The returns from the signal-service stations show that an excess of rain over the mean for the month has fallen on the Atlantic coast, except in Maine and Southeastern Connecticut, and throughout the Middle States and lower lake region, excepting western Lake Erie. This surplus amounts to 4.32 inches at Jacksonville, Fla., 4.01 at Rochester, and 7.07 at Norfolk, but is less at other stations in the sections, varying from 1 to 2 inches. A slight excess has also fallen in the western portions of Tennessee and Minnesota, and eastern parts of Nebraska and Kansas. There has been a deficiency of about an inch in northern New England, interior portions of South Carolina and Georgia and throughout the Gulf States, excepting Florida, while in Central and Eastern Tennessee, Western Kentucky, the Upper Mississippi Valley and over the upper lake region the figures show a general deficiency of about 2 inches. The precipitation has been very slight at the Rocky Mountain stations and on the Pacific coast, apparently less than the mean for October.

TEMPERATURE.

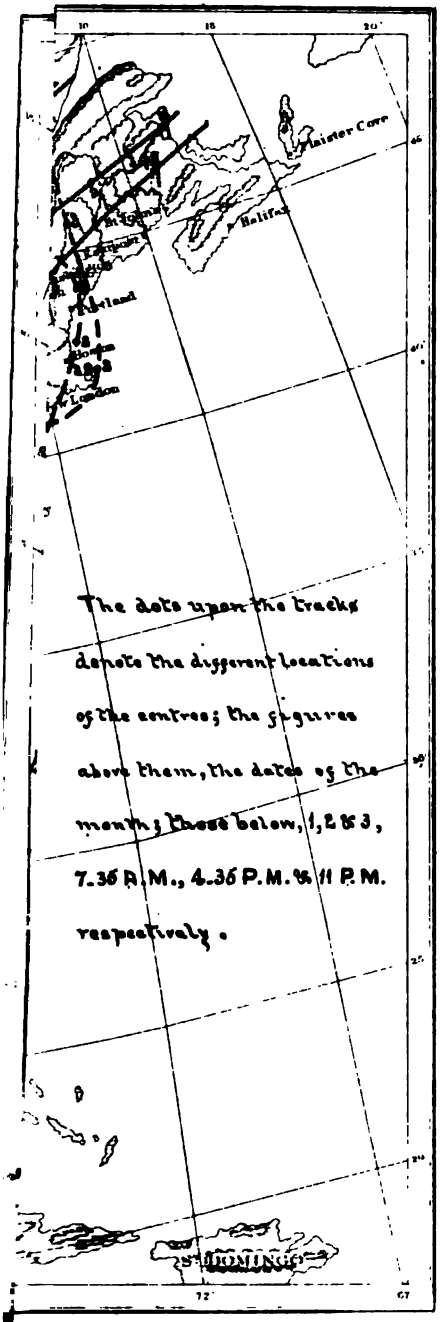
The mean temperatures for this month show but little variation from the means for October at most of the signal-service stations. At the Rocky Mountains, on the Pacific, and western Gulf coasts, in Eastern Iowa and Southern Wisconsin, and throughout the Atlantic States, from Florida to Rhode Island, temperatures slightly cooler than usual have been experienced, the variation below the mean for the month being greatest at Milwaukee and on the coast of Georgia and the Carolinas where it amounts to about 3°. In all other sections the temperature has been slightly above the mean for October. The month has, however, been much cooler than October, 1871, everywhere in the Mississippi Valley and eastward, this difference of the mean temperature being greatest in Florida, Georgia, and from the Ohio Valley to the lower lakes and southern portion of the upper lake region, amounting in these sections to from 3°

MONTHLY WEATHER-REVIEW, NOVEMBER, 1872.

STORMS.

During this month twenty-four storm-centers have traversed various parts of the country east of the Rocky Mountains. Fifteen of these disturbances have pursued an irregular eastward course from the northwest over the lake region to Canada, or crossing the Saint Lawrence Valley, have traveled eastward over Maine and New Brunswick; two have moved from the Upper Mississippi Valley eastward to Virginia, and thence along the coast to New England; four have crossed the country diagonally from the southwest to New England and the eastern British provinces; one from Texas across the northern portion of the Gulf to Florida; and two, which were probably central at a distance from the coast, have been felt along the Atlantic sea-board.

Destructive gales have attended the progress of many of these storm-centers, particularly over the upper lake region, in the Saint Lawrence Valley, and on the middle and east Atlantic coasts. Their approach has, however, been heralded by the display during the month of sixty-eight cautionary-signals at the lake stations — fourteen on the Atlantic coast and six on the Gulf.



RAIN-FALL.

Notwithstanding the number of storms which have visited the country during the month, the returns from the signal-service stations show that the precipitation has been generally less than the mean for November at the Rocky Mountain stations, Florida, the Southwest, (except Southeastern Texas and Southern Louisiana,) the Northwest, the Ohio Valley, and throughout the lake region. The figures show this deficiency to be greatest over the section of country extending from Kansas eastward to Kentucky and Ohio, averaging about 2 inches, but amounting to over 4 inches in Central Iowa. An excess of rain has fallen in the Carolinas, Georgia, Eastern Tennessee, Central Alabama, Southern Louisiana, and Southeastern Texas, while about the average quantities are reported from the Middle and Eastern States, except the western portions of Pennsylvania and New York, where the amounts are below the mean.

TEMPERATURE.

The mean temperatures for the month at the various signal-service stations show that the month has been colder than usual everywhere from the Atlantic to the Rocky Mountains, excepting, perhaps, in Montana. Areas of high barometric pressure attended by low temperatures for the season, have, in several instances, followed closely after the storm-centers, causing cold "northers" in the Southern States, and severe cold, westerly gales over the Northwest and upper lake region. The variation

ure below the mean for November has, consequently, been greatest in amounting to from 3° to 8°. Compared with November of last year lower ave prevailed everywhere east of the Rocky Mountains, except in New York, New Jersey, and Eastern Pennsylvania. Thus the mean temperature the same for November, 1871, by 3°.1 at New London, 3°.3 at Portland, t Burlington, Vt., but lower by 5°.1 at Savannah, 7°.4 at Jacksonville, obile, 7°.6 at Cincinnati, 4° at Saint Paul, and 4°.8 at Escanaba, Mich.

MONTHLY WEATHER-REVIEW, DECEMBER, 1872,

STORMS.

month no less than twenty-seven storm-centers have been traced in their various parts of the country upon the War Department weather-maps, United States Army. Two of these storms have apparently traveled the country from the Pacific coast, but the paths of the remainder are d to the country east of the Rocky Mountains, and are about equally en the two favorite winter-routes of these disturbances, the one from the tward over the lake region and northern New England to the eastern ces, and the other from the southwest northeastward to the Middle w England, or eastward along the Gulf coast, thence following the trend c coast northeastward toward Nova Scotia. The usual attending high les of the winter storms have been experienced in nearly all parts of the their approach has been announced by the display of forty-two cautionary- lake ports, thirty-two on the Atlantic coast, and three on the Gulf.

RAIN-FALL.

s from the signal-service stations show that an excess of rain, amounting 5 inches above the mean rain-falls for December, has, during the month, xas, Louisiana, and Western Mississippi. A surplus, varying from 1.12 9 inches, has also fallen in Southern Virginia, North Carolina, Eastern nterior portions of South Carolina and Georgia, and in Northeastern all other sections east of the Rocky Mountains (excepting at New London, eavenworth, and Breckenridge, which exhibit amounts slightly above the gures show that the fall of rain and snow has been less than the average r. This deficiency is comparatively small for New England, the Middle ower lake region, but is large in Western Tennessee, the Ohio and Upper alleys, and over the country adjacent to Lakes Michigan and Superior, the having been scarcely one-fourth as much as the average for the month ions in these sections.

TEMPERATURE.

temperatures for the month at the signal-service stations compared with the ratures for December, as ascertained by a long series of observations, show th has been much colder than usual everywhere east of the Rocky Mount- xcess of cold amounts to from 5° to 7° at stations in all parts of the coun- Chicago, Milwaukee, Leavenworth, Breckenridge, and Rochester it amounts Much colder weather has prevailed than in December, 1871, in all sections erritories, except from Virginia to Southern New Jersey, and from Nebraska llinois, where the temperatures have been about the same. This unusually her may be attributed to the large number of areas of high barometer, or heric waves, which, with their attending low temperatures, have rolled ountry from west to east. No less than fifteen of these areas of high press- en traced upon the weather-maps for this month, while during the corre- onth last year only nine made their appearance.

MONTHLY WEATHER-REVIEW, JANUARY, 1873.

STORMS.

he past month the progress of twelve storm-centers has been traced on the ps of the signal-service. Of these, three have crossed the country in a rd direction from Texas to New England and the British provinces; five

Digitized by Google

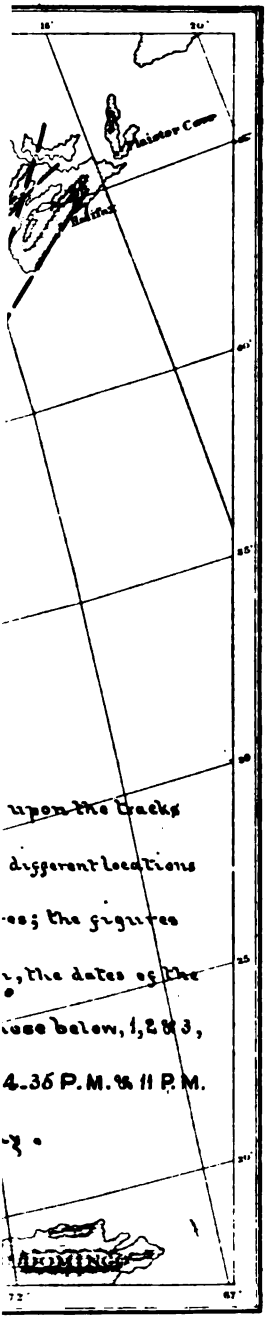
have moved from the extreme northwest eastward over the lakes into Cana
England; one from Manitoba over Lake Superior into Canada; two northea
the Atlantic coast to the Eastern States and Nova Scotia or Canada; and on
gressed eastward through the Gulf States, and thence northeastward up the
Of these storms the most severe have been that of the 7th and 8th in
west, and that which from the 21st to the 24th crossed the country from Tex
Scotia. The westerly winds closely following the center of the former in
strong gales, which, with heavy snow and temperatures far below zero, served
it one of the most terrific which has visited that section for many years.
(that of the 21st) was very extensive in its effects, as during its course nearly
country east of the Rocky Mountains was reached by its rain or snow-belts.
easterly gales were felt with most severity from Lake Michigan to Lake Erie,
snows fell from Kansas and Missouri northeastward to Canada.
Twenty-four cautionary-signals were displayed during the month at poi
middle and east Atlantic coasts, and two on the Gulf coast.

RAIN-FALL.

The monthly rain-fall returns for January from the signal-service stations
there has been in general a deficiency on the Pacific coast; but east of the Rock
ains an excess of rain and snow. This latter excess is most decided in Miss
Jersey, and Connecticut. A small region of deficiency also appears to ex
Kentucky, Tennessee, Mississippi, and Alabama

TEMPERATURE.

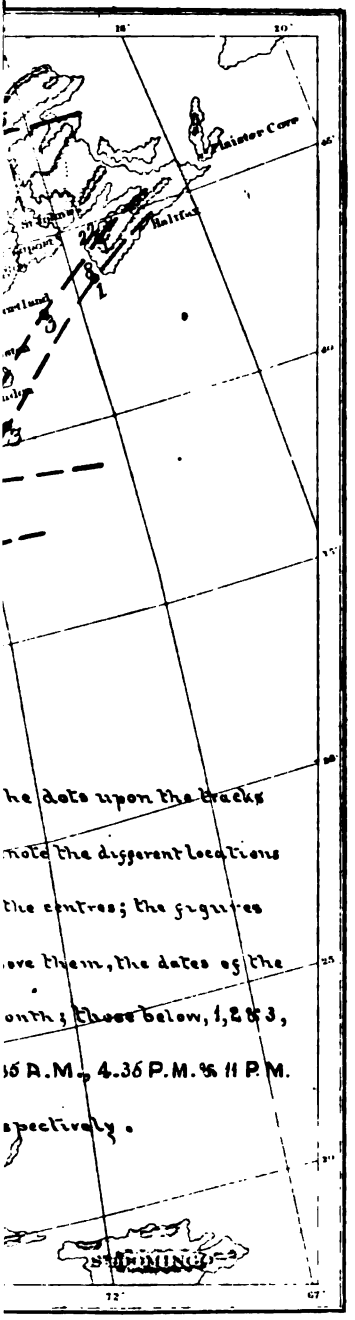
The mean temperatures for January, as given by the signal-service reports,
over the country east of the Rocky Mountains the weather has been genera
than usual. This difference is greatest in the northwestern section, being in
and Northern Ohio about 6° below the mean temperature for the month, and
consin and Minnesota to Kansas ranging from 7° to 12° lower than usual. In
Mississippi Valley, and also Northwestern New York, the average temperat
been from 5° to 6° lower than might have been anticipated, while this diff
New England and throughout the Middle States generally has been from 2°
the South Atlantic States about the mean temperatures have prevailed, except
ern Florida, where they are shown to be somewhat lower, as also in the Gulf



---

MONTHLY WEATHER-REVIEW, FEBRUARY, 1873.

STORMS.



During this month ten different storms have crossed portions of the countr
the Rocky Mountains. The paths of their centers have, approximately, bee
upon the War Department weather-maps, Signal Service, United States Army
That of February 3d and 4th passed over Nebraska, Iowa, Wisconsin, and
into Canada, accompanied by rain, at places heavy, from Texas to Iowa and
to the middle Atlantic coast, but by generally light snow or rain thence n
over New England and the lakes, and by brisk and high winds over the lak
westerly winds being most severe; thunder-storm reported from Knoxville, 4
February 5, 6, 7, and 8.—Over Gulf and South Atlantic States and thence north
off the middle and east Atlantic coasts and over Nova Scotia, accompanied
rain to Massachusetts, and by fresh and brisk winds over Gulf coast, and
high over Atlantic coast, easterly to northerly winds most severe.
February 6 and 7.—Eastward over Northern Minnesota and Lake Superior into
accompanied by areas of very light snow and brisk and high winds over the lak
southwesterly to northwesterly being most severe.
February 9, 10, and 11.—Eastward from Dakota over Minnesota, Wisconsin, an
gan into Canada, accompanied by generally light rain or snow from Misso
nessee, and Virginia northward and northeastward, and by brisk and hig
southeasterly to southwesterly being most severe.
February 11 and 12.—Northeastward over Southern States and beyond middle
coast, accompanied by heavy rain from Kentucky to Southern New Jersey an
ward to Gulf, but snow from Ohio to lower lakes and Connecticut, and by
high southerly to westerly winds over western Gulf coast, brisk and high so
erly over South Atlantic States, and brisk and high easterly to northerly from
to Massachusetts; thunder-storm reported from Knoxville, 12th; storm very
from Cape Cod southward.
February 15, 16, and 17.—Northeastward from Texas over the Ohio Valley; the
ward over and beyond middle Atlantic coast, accompanied by rain, generall

onnecticut and southward to Gulf, but areas of light rain and snow
rd to Maine and the lakes, and by brisk and high winds over western
ic coasts; severe thunder-storm reported from Memphis on 15th.
nd 18.—Northeastward from Dakota over Minnesota and Lake Supe-
r, accompanied by light rain and snow and by brisk and high winds,
temperature.
nd 21.—One over the Southern States, and thence northeast along the
h and brisk southerly winds over west Gulf, veering to high northerly;
over south Atlantic coast, and brisk and high northeasterly to north-
middle and east Atlantic coasts; other northeastward over Missouri;
chigan into Canada with brisk and high winds; the two accompanied
ver the country east of the Rocky Mountains, except snow from Iowa
astward over the Lake region and Northern New England.
nd 27.—From Nebraska and Missouri northeastward over Michigan into
anied by brisk and high winds; at the same time a diminished pressure
ward over Gulf and South Atlantic States, and thence northeast off
Atlantic coasts with brisk and high winds; the two accompanied by
ari to Northern Louisiana and eastward to Virginia and south Atlantic
w thence northward over Northwest, lakes, and Southern New England.
autionary-signals were displayed at the signal-service stations on the
d two on the Gulf.

RAIN-FALL.

ith the means of a number of years for the month, the rain-fall returns
ervice stations show a deficiency over the lake region, Northwest,
hern Georgia and South Carolina, New York, and Northern New En-
ess from the northern portions of Alabama, Georgia, and South Caro-
, Southern Indiana and Ohio, Pennsylvania and Southern New Jersey,
ed over Tennessee, also an excess over Rhode Island and Eastern
d Connecticut.

TEMPERATURE.

n temperature for the month, taken from the signal-service reports
th that for a number of years at the same stations, or close by, it is
former has been somewhat higher over the Gulf States, eastern por-
y and Tennessee, and southern portions of Ohio and Indiana, by from
erwise east of the Rocky Mountains lower by from 1° to 8°, being
New York, Michigan, Wisconsin, and Minnesota.

MONTHLY WEATHER-REVIEW, MARCH, 1873.

STORMS.

onth eleven storms have crossed portions of the country east of the
. The paths of their centers have approximately been traced upon
ent weather-maps, Signal Service, United States Army.
hat of March 1, 2, 3, and 4, passed from Texas over the Gulf States as
ure on the 1st and 2d, accompanied by heavy rains and brisk winds,
o high northerly along the Texas coast on the 1st and 2d; thence
ng the Atlantic coast, followed by brisk and high northerly to west-
outh Atlantic and Middle States, but brisk and high northeasterly,
esterly over east Atlantic coast, and accompanied by heavy rain over
ic States, but by generally light snow over the Middle and Eastern
llowed on the 2d and 3d by very cold weather and brisk and high north-
om the northwest and upper lakes to the Gulf, which, on the 3d and
ward over the Atlantic coast; on the 3d, thermometer readings from
elow zero were reported from Minnesota.
3.—Nearly due east over Dakota, Minnesota, and Upper Michigan into
by rain and brisk to high easterly and southerly winds from the
Valley and Tennessee to the lakes and northern portions of the Mid-
tates; followed by occasional snow over the lakes and Minnesota,
igh westerly winds from the Missouri Valley eastward over the Mid-
ates, increasing to gales over the lakes.
0.—From Southern Dakota, a little south of east over Iowa, Illinois,
diminished pressure, accompanied by fresh and brisk winds only;
er Ohio, Pennsylvania, and beyond Cape Cod increasing in severity,
h winds and generally light rain or snow from Tennessee and North
nd thence to Maine.

MONTHLY WEATHER-REVIEW, MAY, 1873.

STORMS.

During this month ten storms have traversed the country east of the Rocky Mountains. The accompanying map shows the paths of their centers:

I. *May* 1, 2, and 3.—Apparently originating on the last day of April in the Rocky Mountains, the center of this storm progressed eastward over Kansas, Missouri, Northern Indiana, Southern Michigan, and Lake Erie, moving thence southeastward over Pennsylvania and Maryland to the Atlantic, sending out a branch on the 2d over Ohio, Virginia, Chesapeake Bay, and thence off the coast. Its passage was attended by heavy rains and brisk and high winds from the Mississippi to the Atlantic, sleet and snow falling in New England.

II. *May* 4 to 8.—Appearing first in Southern Texas, this storm moved slowly northeastward over Arkansas, Missouri, Illinois, Southern Michigan, and Lake Huron. The highest winds during its passage were experienced on the coast of Texas, the lower lakes, and the middle Atlantic coast.

III. *May* 8 and 9.—Developed among the mountains of North Carolina and moved northeastward along the middle Atlantic coast, accompanied by heavy rains and high winds.

IV. *May* 8, 9, and 10.—Appeared first in Kansas and moved eastward over Missouri, and thence rapidly northeastward over Illinois, Indiana, Michigan, and southern Lake Huron into Canada. Heavy rains fell in Northern Illinois and Eastern Iowa, and a belt of lighter rains and brisk winds, from four hundred miles to eight hundred miles in width, attended its progress.

V. *May* 10, 11, and 12.—Like III, this storm seemed to develop among the mountains of North Carolina, passing northeastward over Virginia, eastward over Chesapeake Bay, and again northeastward along the coast to New Brunswick.

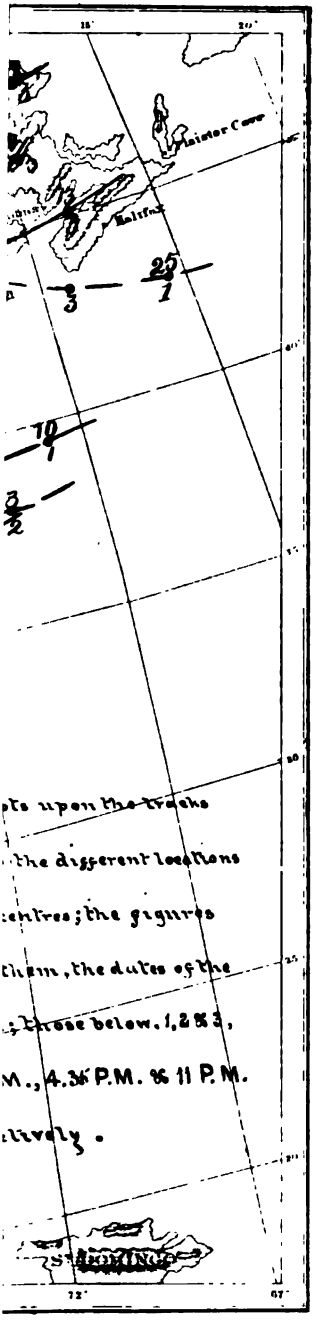
VI. *May* 12 and 13.—Traveled from Minnesota very rapidly eastward over the lakes, Saint Lawrence Valley and northern New England to Nova Scotia, causing light rains and high winds throughout its course.

VII. *May* 13, 14, and 15.—From the plains of Kansas and Indian Territory this storm-center moved eastward over Southern Missouri, southeastward into Alabama, and then again eastward off the coast, rapidly diminishing in intensity after crossing the Mississippi. Considerable rain fell in all the Southern States, except Texas, but no dangerous winds were reported.

VIII. *May* 18, 19, and 20.—Developing in the southwestern plains this depression traveled rather slowly northeastward from the Indian Territory over Lakes Michigan and Huron into Canada, attended by rain-belts and fresh to brisk winds throughout the lake region and western and northwestern sections of the country.

IX. *May* 21 to 24.—From Montana this disturbance moved slowly eastward over Dakota, crossing, with somewhat increased velocity, Minnesota, the upper lakes, the Saint Lawrence Valley, Maine, and Nova Scotia, causing, by its slow progress, several days of cloudy and rainy weather over the entire northern portion of the country. It was during its passage over the Northwest that the terrible and destructive tornado swept through Iowa.

X. Two depressions, one slowly descending from the Upper Missouri Valley, the other moving northward over Kansas and Nebraska, seemed to unite in Southern Dakota to form this storm-center. From Dakota it moved southeastward into Iowa, northeastward to Lake Superior, and thence nearly due east over the Saint Lawrence Valley, Maine, and New Brunswick. Its rain-belts reached nearly the whole country east of the Mississippi, and brisk winds, increasing occasionally to high, were experienced throughout the northern sections.



TEMPERATURE.

The temperatures for the last month were generally lower than for May, 1872, the chief exceptions being Key West, Oswego, and Grand Haven. As compared with the mean May temperatures of a series of years, the thermometric figures for May, 1873, show excess of warmth over northern Lake Michigan, Northern Michigan, Lake Huron, Southern Ohio, Kentucky, Tennessee, and Eastern Massachusetts, but a deficiency of temperature in Kansas, Missouri, Iowa, Minnesota, Wisconsin, Indiana, Illinois and the Gulf States, Florida, and Southeastern Georgia, and generally throughout the Atlantic States and the lower lake region. The regions of minimum rain-fall and thermometric maxima nearly correspond.

RAIN-FALL.

As compared with the mean May rain-falls, the rain-fall returns of last May show deficiencies in the northern and western parts of Lake Superior, Lake Michigan, and in the entire country stretching from the Saint Lawrence Valley to Maine, and thence over the lower lakes, Western New York, and Western Pennsylvania, West Virginia,

ral Indiana, and Southeastern Illinois. Excess of rain occurred in Iowa, Mis-
ern Kansas, East Tennessee, and also along the Atlantic sea-board, except
and, Me., and Savannah, Ga., and a very great excess, from 2.00 to 14.58
r the Gulf States.

RIVERS.

r reports for the month show a slight decline in the Red and Missouri Rivers
eginning to the middle of the month, after which a decided rise occurs until
The Arkansas rose slowly at Little Rock until the 23d, after which it subsided
he Mississippi has alternately risen and fallen; at Saint Paul the water was
r on the 19th than on the 31st, at which dates, respectively, it was lowest
t; at Saint Louis the lowest and highest extremes occurred, respectively,
and 31st, the difference being 6 feet and 3 inches. At Cairo the river
t on the 28th and highest on the 16th, the extremes being about 13 feet.
is the difference between the highest and lowest water for the month has
9 feet, having been highest on the 22d and lowest on the 28th. A very
occurred on the Cumberland at Nashville from the 1st to the 4th, after which
radually subsided until the 21st, rising again until the 27th, and then again
il the 31st.
) was affected by a great swell which traveled from Pittsburgh on the 4th
lle on the 14th; since then it has fallen almost uninterruptedly. The differ-
en the highest and lowest water has been 15 feet at Pittsburgh, 19 feet at
3 at Cincinnati, 7½ at Louisville, and 16½ at Evansville.
cations are that the Missouri and its tributaries will continue to rise.

MONTHLY WEATHER-REVIEW, JUNE, 1873.

STORMS.

his month ten disturbances have crossed portions of the country east of the
ntains. The accompanying map shows, approximately, the paths of their
he figures above them are the dates of the month; those below, 1, 2, and 3,
spectively the time of the morning, afternoon, and midnight observations;
on them show the location of the centers at each observation.
ter of that of June 1 and 2 moved over Eastern Florida into Southern
d disappeared, producing heavy rains and brisk winds.
d 4.—From Dakota over Iowa, Lake Michigan, lower lakes, New York, and
nd; accompanied by fresh and brisk winds over the Northwest, lakes, and
ates, and by rain, at places heavy, east of the Rocky Mountains, except on
ast.
9, 10, and 11.—From Dakota over Minnesota, the lake region, and northern
nd; with rain, generally heavy, fresh and brisk winds, and occasionally
der-storms, over the northern portion of the country.
13, 14, and 15.—One southeastward over Minnesota to Lake Erie, and thence
nto Canada, causing thunder-storms, with rain-areas, generally light, and
ccasionally brisk winds from the Ohio Valley to the lakes; a second, appa-
loping in the Southern States, thence eastward to the coast and northeast-
robably Nova Scotia, with fresh and brisk winds and rain-areas on the coast.
5, 16, and 17.—Over Dakota, Lake Superior, and thence probably over
ucing areas of light rain and fresh and brisk winds over the northern portion
le States and the lake region.
9, and 20.—Over Northern Minnesota, Lake Superior, and thence over Maine
cotia, attended by occasional rain-areas and brisk and high winds over the
lake region, and New England.
2, 23, and 24.—From Dakota over Southern Minnesota to Iowa, then break-
and sending out to the eastward several minor disturbances, producing
der-storms of short duration from Missouri and the Ohio Valley northward.
6, 27, and 28.—Eastward over Northern Dakota, Minnesota, Lake Superior,
n New England, sending a branch over Iowa, with severe thunder-storms
see to the Northwest, lakes, and New England.
9, and 30.—Over Minnesota and the upper lakes into Canada, accompanied
hunder-storms north and west of the Ohio Valley, brisk winds over the
ake region, and Atlantic States, and rain, often quite heavy, from the Lower
Northwest and lakes to the Atlantic coast.
mary-signal was displayed at Duluth on the 17th.

TEMPERATURE.

temperature for June, 1873, is higher than the mean for the month, except
ty of Lake Superior, where it is lower by 0°.7 to 1°.8; in the South Atlantic
es from 1°.6 below to 1°.0 above, and from New Jersey and Eastern Penn-
Maine, 1°.2 below to 1°.1 above. The excess is greatest in Northeastern
; Northern New York, 1°.1 to 4°.7; Kentucky, Ohio, Indiana, and Southern

Digitized by Google

Michigan, 1°.7 to 6°.5; Southern Alabama, 4°.9; Illinois, Southern Wisconsin, and Eastern Iowa and Missouri, °.5 to 2°.1; Eastern Kansas, 4°.2; Southern and Western Minnesota, 4°.8 to 6°.7; Fort Sully, Dakota, 8°.0, (†) and Cheyenne, 4°.4.

The mean for June, 1873, is lower than that for June, 1872, at San Francisco, 1°.1; the Gulf States, 0°.4 to 1°.6; in the South Atlantic States, 0°.3 to 2°.0; in the vicinity of Lake Superior, 0°.4 to 1°.6. It varies in the Middle, Atlantic, and New England States from 1°.1 above to 3°.9 below. The former is the higher in Iowa and Southern and Western Minnesota, 4°.5 to 5°.5; in the Ohio Valley, 1°.0 to 4°.7; over the lake region, 1°.1 to 2°.7.

New Orleans	70.8	76.0	82.5	70.4	75.8	80.5	66.9	73.7	

RAIN-FALL.

The returns for the month from the signal-service stations show that there has been an excess of rain over the mean from Florida to Western Tennessee, and westward to Arkansas and Eastern Texas, varying from 6.50 inches to 0.86 inch, from Eastern South Carolina to Southern Virginia 1.29 inches to 0.60 inch, from Central Indiana to Southeastern Missouri 1.42 inches to 0.68 inch, over Northeastern Ohio 1.23 inches, and from Eastern Nebraska northeastward to Eastern Minnesota and Northern Wisconsin and over Northern Michigan 4.34 inches to 0.45 inch.

There has been a deficiency in New England varying from 1.79 to 4.00 inches, the Middle States, except Southern Virginia, 0.44 to 3.26 inches, from northern portion of Georgia and South Carolina to the Ohio Valley 0.35 to 2.03 inches, from Northeastern Kansas to Southern Wisconsin and Northern Illinois 1.67 to 3.90 inches, over Northwestern Ohio and Southeastern Michigan 0.29 to 1.23 inches, and over Western Minnesota 0.98 inch.

RIVERS.

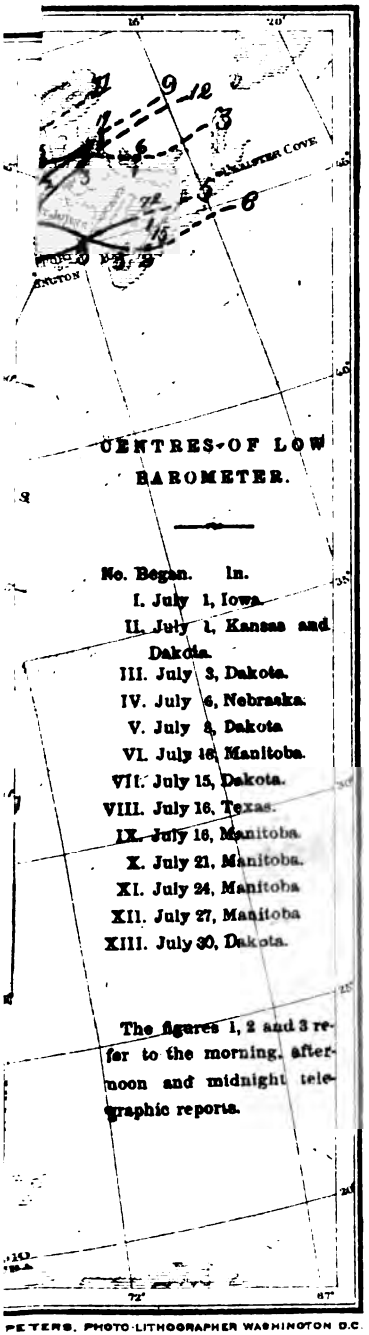
The Red River rose steadily at Shreveport during the first week, after which it remained nearly stationary until the 28th, when it began to fall slowly.

The Arkansas fell and rose alternately during the first twenty days, then fell steadily, having been eight and a half feet lower on the 30th than on the 1st.

The Missouri at Fort Benton rose steadily until the 19th. Throughout the lower portion of the river an almost continuous rise occurred, although a slight fall was observed between Kansas City and Brunswick after the 26th.

The Mississippi fell slowly at Saint Paul and between Cairo and New Orleans, (excepting some slight oscillations,) the difference between highest and lowest water for the month being at St. Paul nearly five feet, between Cairo and Vicksburgh nearly seven feet, and at New Orleans eleven inches; between Le Claire and Warsaw a gradual rise occurred from the 4th until the middle of the month, after which a steady fall was observed; at Saint Louis the water rose slightly between the 3d and 11th, falling slowly after that date.

The Cumberland at Nashville fell from the 1st to the 9th, then rose until the 14th, fell again until the 27th, rose until the 29th, but on the 30th it began again to fall, the difference between highest water (19th) and lowest water (9th) being six feet.



The Ohio, at Marietta and above, as well as its tributaries, has changed comparatively little; from Cincinnati to Evansville it has fallen almost continuously—the difference between highest and lowest water being nearly nine feet at Cincinnati, seven at Evansville and three at Louisville; at Paducah the water fell from the 1st to the 13th, rose until the 21st, falling again from that date until the 30th.

MONTHLY WEATHER-REVIEW, JULY, 1873.

STORMS.

During the month of July, 1873, thirteen areas of low barometer have been recorded on the daily weather-maps of the Signal Office; the tracks pursued by these will be found on the accompanying map No. 1; they have in general passed centrally over

northern limit of the United States. This feature has indeed been this year more noticeable than in former years, as is seen from the following statement:
71. The mean latitude of the tracks of 15 centers of low barometer was 45°.
72. The mean latitude of the tracks of 14 centers of low barometer was 44°.
73. The mean latitude of the tracks of 13 centers of low barometer was 47°.
former years during this month, so in the present year, with scarcely an exceptions areas of low pressure first became apparent in or beyond Dakota and Manitoba. On most occasions the appearance of a low barometer in the Northwest has preceded by slight barometric depressions on the coasts of Oregon and California, as been impossible to decide whether the disturbances have passed from the Ocean eastward or have originated in the Rocky Mountains of British America. numerous local storms that are experienced during the summer months have a relation to the large areas of high and low barometer, to the topography of the , the position of the ocean and other bodies of water, &c., &c., all of which may be understood from map No. 2, on which are drawn with some approach to correct the lines of equal storm frequency for the month of July. The local storms are almost invariably attended with lightning, &c.) have been most numerous da, on the west and southwest side of the area of high barometer that prevails July on the Atlantic, between the latitudes of 12° and 30° north. The region greatest frequency is in Ohio and Western Pennsylvania, where the south and est winds attending the areas of low pressure rise up over the high country of tates. The storm frequency diminishes as we proceed from the Gulf coast ard over the low, flat country and northwestward toward the high arid plains; ther hand it increases as we proceed from the middle and east Atlantic coasts d up a rapid slope to the summit of the Appalachian range. The local storms t frequent on the dry plains west of the valley of the Mississippi River, and e indications of a region of diminished frequency in the northern part of the e of Ontario, though this may possibly be due to the scarcity of our stations in ion.

WINDS.

inds of special severity have been reported during this month, except the tor- July 3, at Indianapolis. The winds have reached the limit of *high* (a velocity miles an hour) only twice in the Middle Atlantic States and thrice in Dakota thern Minnesota. The prevailing winds (by which is merely meant the wind been recorded the greatest number of times) are shown by arrows on map No. which we also perceive something of the connection between the winds and ars. In general it may be stated, that south and southeast winds have pre- the Gulf States, Iowa, and Minnesota, but elsewhere over the country east of ky Mountains the prevailing winds have been from the south, southwest, and

RAIN-FALL.

tal amount of rain during the month appears to have been in excess in Indinois, and Michigan, and on the southern border of Lakes Superior, Erie and as also in New England. The reports from the summit of Mount Washington ain-fall of 13.5 inches, as contrasted with only 3.5 inches in July, 1872. On the nd the rain-fall of June was 3.5 inches, while in June, 1872, 18.5 inches were ; by combining the two we obtain for June and July together, in 1872, 22 nd in 1873, 17 inches. A deficiency of rain is apparent in the province of Onthe middle Atlantic coast, over the Lower Mississippi valley and in the Northhe details of the rain-fall are given for each geographical subdivision in the nying table.

Table showing the rain-fall and temperature for July, 1873.

District.	Average rain-fall.	Average temperature.
	Inches.	*Degrees.*

TEMPERATURE.

The temperature has very generally averaged one or two degrees lower than corresponding month of 1872, which latter was indeed in many places one of the warmest on record. Compared with the average of many years, the past month seems have been from one to four degrees warmer than the normal temperature over Middle Atlantic and the Eastern Gulf States. In general, however, over the the country east of the Rocky Mountains the temperature has been slightly below average, the deficiency amounting to one or two degrees in the valley of the Mississippi River.

The accompanying table shows for each geographical subdivision the general temperature, as observed and as compared with normal values resulting from years of observation.

The details of the distribution of temperature may be seen from the isotherms given on map No. 3, and which hold good for the general surface of the earth.

The monthly range of temperature, or the difference between the highest and temperatures that have occurred during the month, is given by the lines of monthly range on map No. 4. It will be seen that the range is greatest in the dry localities, and least in low and damp regions. The range also increases with the latitude, even on the Atlantic coast, a phenomenon doubtless due to the changes in cloudiness and humidity.

RIVER AND OCEAN TEMPERATURES.

Reports have been received for the last ten days of the month from seven stations that have, at the suggestion of the United States Commissioner of Fisheries, been furnished with apparatus for observing the temperatures of the in the rivers, bays, &c.; the results promise to be of general meteorological The general results of these observations (the first of their kind) are given in printed on the border of map No. 3, where the comparison may easily be made the temperature of the water and that of the air, &c., &c.; the water-temperatures refer to the lowest stratum of water near the bottom of the river or bay, and vations are made daily at 3 p. m.

In general it is found that the range of temperature increases very regularly proceed from Cape Hatteras northeastward. The figures for each day show temperature steadily increased at Boston and New London from the 1st to and then began as steadily to diminish. This change may be due either to a fluence or to a change in the warm currents of the adjacent ocean.

RIVER-OBSERVATIONS.

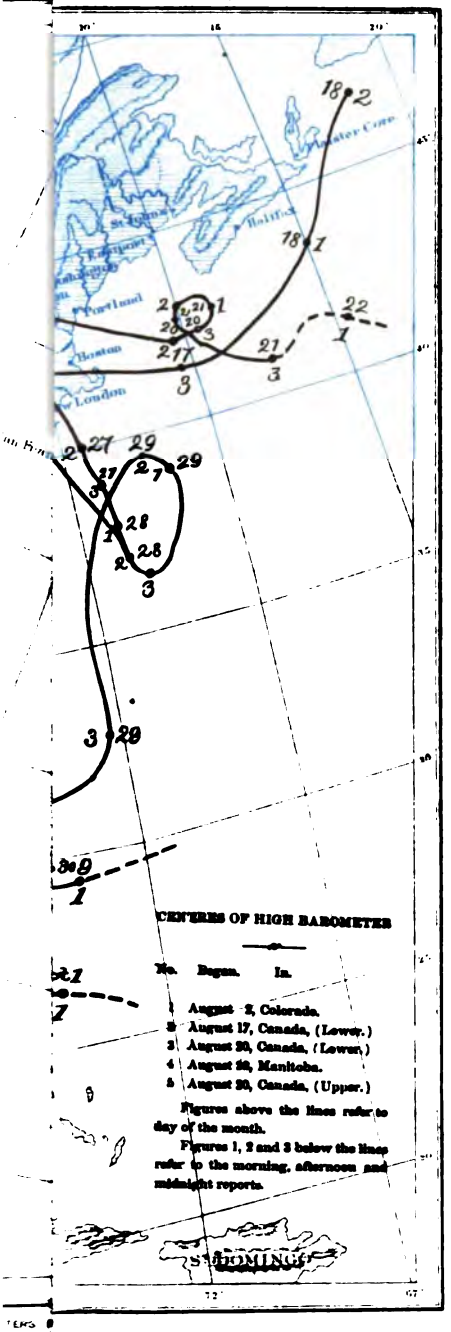
A general view of the results of observations of the water in the rivers the table accompanying map No. 3. In addition to this table, the following only are necessary. The Red River fell steadily during the entire month. souri fell almost continuously, except at Leavenworth, where it rose during week of July. The Upper Mississippi has declined somewhat; the middle the river was at first stationary or slightly rising, and then began to fall steadily lower portion of the river, after falling and rising, has again begun to fall. berland has experienced three sudden rises and subsequent falls, attended periods of rain. Similar oscillations have occurred in the Ohio, a specially having moved from Pittsburgh to Louisville between the 6th and the month.

CAUTIONARY SIGNALS.

No cautionary signals have been displayed during the month.

MONTHLY WEATHER-REVIEW, AUGUST, 1873.

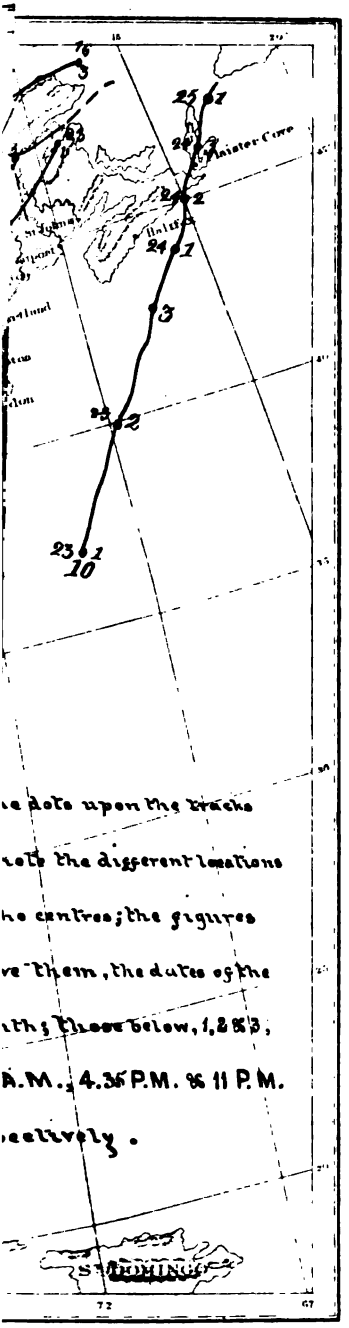
The general meteorological conditions as determined from the observations the stations of the Signal-Service, United States Army, during the month 1873, are indicated upon the accompanying maps.



In comparing these conditions with those of the corresponding period years, the most noticeable features are—

1st. The excess of barometric pressure over New England and the Middle States.

2d. The diminution of temperature below the mean for the month of Avious years, in the districts above named, and thence westward to include lake region and the adjoining States.



3d. The unusual quantity of rains in the Middle Atlantic district, esp the coast.

The paths of the centers of the several areas of high barometer are traced on map
. 1.
These areas, with but one exception, were first observed in British America, after
ich they moved with such uniformity, and became so unusually well defined as to
der it possible to locate their centers at each of the tri-daily reports of this office
n the time of their first appearance until they finally passed beyond the limits of
ervations.
The general direction of these paths while the areas remained central on the conti-
t, is approximately from the northwest to the southeast, but for want of more ex-
ded observations their final direction after passing off the coast remains as yet un-
ermined.
During the month of August, 1873, twelve areas of low barometer have been traced
the tri-daily weather-maps, and the tracks pursued by the centers of these areas,
h explanatory notes, are represented on map No. 2. Track No. 2 may be found on
map accompanying the weather-review of July.
hese areas of low barometer were, with one exception, first observed either in the
itories of the United States east of the Rocky Mountains or in Manitoba; and by
rring to map No. 3, it will be found that this region is one of mean low barometer
the month. Seven of these areas passed eastward to the Atlantic coast within the
its of our stations, with a mean latitude of 43°.
he remaining areas passed to the northeastward into British America without any
ided atmospheric disturbance in the United States.

STORMS.

he areas of low barometer traced on map No. 2 were accompanied with slight dis-
ance while in the western portion of the United States, but no marked change in
weather occurred until the 11th of the month, when the area of low barometer
ked No. 6 was first observed in Kansas.
his storm moved slowly to the eastward, with cloudy weather, rain, and light to
h winds, the winds increasing in force as the center approached the Atlantic coast,
finally producing the northeasterly gale which occurred on the middle Atlantic
New England coast on the 14th and 15th. For this storm cautionary signals were
layed at Cape May, New York, New London, Wood's Hole, Boston, Portland, and
tport.
he second storm, and by far the most severe one that has occurred since the estab-
ment of the signal-service, is traced as No. 10 on map No. 2. Although this storm did
occur within the limits of our stations, there were indications of some atmospheric
rbance off the middle Atlantic coast on the 23d which warranted the prediction
e in the Probabilities written from the afternoon report of that date, viz, "For the
England and middle Atlantic coast, threatening weather," and from the midnight
rt of the same date, "For the New England and middle Atlantic coast, stormy
ther," with cautionary signals at Cape May, New York, and New London.
his storm, in consequence of its severity, is one of unusual interest, and the course
ked for it may vary from the actual, which cannot be determined until additional
have been obtained, when a complete and accurate description will be published
his office.
he third decided storm of the month was first observed as an area of low barometer
e western portion of Kansas on the 29th at 11 p. m. This area moved to the east-
l over the lake region without any marked disturbance until the night of the 31st,
n brisk and high winds, with areas of rain, were reported. On the morning of the
f September it had become unusually well defined in the lower lake region, after
h it passed over Northern New England and off the Atlantic coast with increasing
, finally producing a violent storm since reported from vessels which were in the
h Atlantic on the 2d and 3d of September.

WINDS.

part from the storms above referred to, no winds of special severity have been
rted, except from Dubuque, Iowa. At this station a violent tornado occurred on
7th, which, although entirely local in its nature, developed an unusual force and
ed great destruction of property. Owing to the carrying away and destruction of
nemometer at this station no recorded velocity of this wind has been obtained.
e unusual velocity of one hundred miles per hour was reported from Mount Wash-
on, N. H., during the storm of the 16th. The force developed by this wind has not
equaled at any other station since the establishment of the signal-service.
e direction of the prevailing winds of the several stations is indicated by the
ws on the map No. 3, and in comparing these directions with the isobarometric
on the same map, it will be observed that they incline toward the area of mean
barometer.

RAIN-FALL.

The total quantity of rain during the month, as deduced from the report several geographical sections, is given in the accompanying table on map No. 4. Middle Atlantic States and in Minnesota there has been a decided excess o mean rain-fall as calculated from observations of previous years; while th been about the usual amount in the South Atlantic and Eastern Gulf State remaining districts there has been a deficiency. In the table referred to the q of rain given has been deduced by taking the general average of the reported rain-f the several stations in each district. The general distribution of the rain-fall, as from the reports received at this office and presented in the table above refer graphically represented on map No. 4.

TEMPERATURE.

In New England, the Middle States, and thence westward over the lower la and adjoining States, the mean temperature has been from two to five degre the normal, and about three degrees above the normal in the upper lake r Upper Missisippi and Lower Missouri Valleys, but in the districts last named t perature has been lower than reported for August, 1872. The results of the tions for the month are given in the accompanying table, in which is noted parison of the temperature of the several districts, with the mean temperatur from observations of previous years. The isothermal lines for the month, g map No. 3, indicate the general distribution of temperature throughout th States.

RIVER AND OCEAN TEMPERATURES.

The number of stations supplied with the necessary apparatus for determ temperature of water has been greatly increased, and the observations w commenced during July have been continued and promise to be of genera ological interest.

The table given on map No. 3, presents a general synopsis of these obs The temperature noted is that of the lowest stratum of water at the place of tion.

RIVER-OBSERVATIONS.

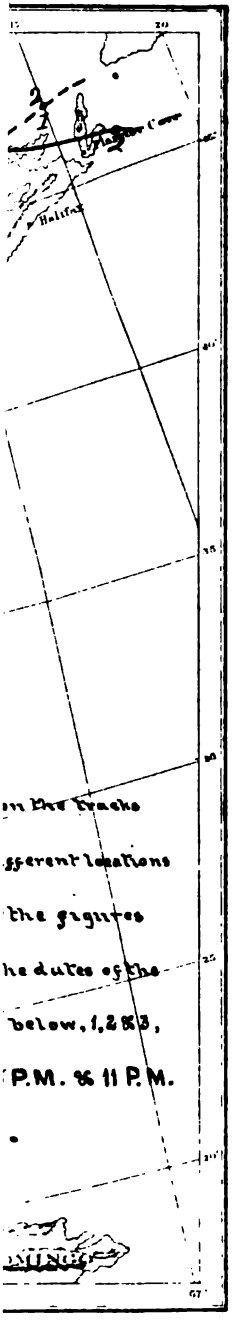
In general these observations show that the rivers draining the eastern sl Rocky Mountains were steadily falling during the entire month; and that th ing the western slope of the Appalachian range, experienced fluctuations a the rains of these districts. The table on map No. 3, presents these observa consolidated form.

MONTHLY WEATHER-REVIEW, SEPTEMBER, 1873.

STORMS.

During this month eleven low barometers have crossed the country east of t Mountains. Map No. 1 shows, approximately, the paths of their centers w passed over the lake region in a northeastward or eastward course, excepting on the South Atlantic coast. Several of them were remarkably severe over t lakes, and destructive to shipping.

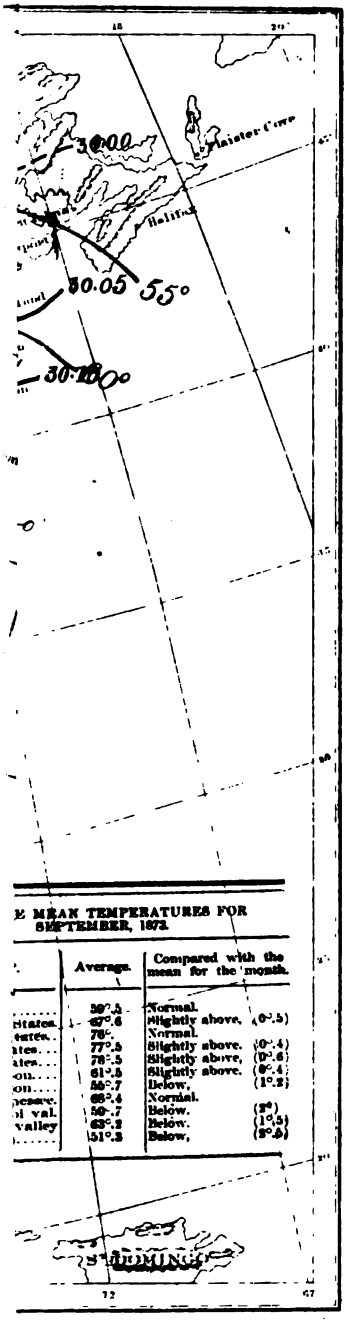
That of August 30, 31, and September 1, was accompanied by occasional brisk winds over the Northwest, Ohio Valley, lake region, Middle States, England, the winds increasing to high from Michigan eastward over the lo and Saint Lawrence Valley.



September 2, 3, 4, and 5, by brisk and occasionally high winds and rain Northwest eastward over the lake region, Ohio Valley, Middle States, and New A hurricane was reported as having lasted about one hour on Lake Mich tornadoes in Massachusetts on the 4th; very severe thunder-storms, with h in Eastern Tennessee on the 3d, and Southeastern North Carolina on the 5th.

September 11, 12, and 13, by rain at nearly all of the stations east of th Mountains; brisk and high winds over the Northwest and upper lakes; severe in Texas on the 13th; heavy snow on Mount Washington on the night of the

September 14, 15, and 16, by high south and west winds over the North upper lakes; occasional rain over Minnesota, the lake region, and New Engl



September 17, 18, and 19, by high winds over the Northwest, lakes, and St rence Valley; by rain from the Northwest eastward over the lakes, Ohio a Lawrence Valleys, Middle States, and New England.

September 18, 19, and 20, by brisk and high winds and heavy rain from Florida to Southeastern Virginia, having been very severe on the coast.

September 22 and 23, by brisk winds and heavy rains on the South Atlantic coast.

September 23 and 24, by high winds over the Northwest and lakes; rains from the Missouri and Ohio Valleys to the lakes and Middle and East Atlantic coast. This was the severest storm of the month, especially on the upper lakes, whence very heavy gales were reported.

September 25 and 26, by high winds over the Northwest and upper lakes, with occasional rain; light snow in Montana on the 26th; heavy gales on the upper lakes.

September 27, 28, and 29, by high winds on Lake Ontario and the lower Saint Lawrence Valley; rain in all sections east of the Rocky Mountains, except the east Gulf States; followed by a severe "norther" in Texas during the night of the 29th and the morning of the 30th, and by light snow from Northern Minnesota and Dakota northward.

On the 7th, 8th, and 9th, an area of high barometer extended itself eastward over the Northwest, lake region, Ohio Valley, Middle States, and New England, with falling temperature, and with light frost over the Northwest and upper lake region.

13, 14, and 15.—A second, over the same region with quite heavy frost, which was very severe on the morning of the 13th over Dakota, Minn., and the northern portion of the upper lake region.

16 and 17.—A third over the Northwest, lakes, Middle States, and New England, with frost over the northern portions of these sections.

September 19, 20, and 21.—A fourth, from the Northwest over the lakes, Ohio Valley, Middle States, and New England, with frost, except probably on the immediate coast.

September 29 and 30.—A fifth, from the Northwest south and east over the entire country, with low temperature, producing frost over the northern sections.

TEMPERATURE.

On map No. 2 will be found a table of the average mean temperature for the different districts for this month. For New England, the South Atlantic States, the Ohio Valley, and Tennessee, it is the same as that for many years. For the Middle Atlantic and Gulf States, and the lower lake region, the former is the greater, from 0°.4 to 0°.6. For the upper lake region, Minnesota, and Upper Mississippi and Lower Missouri Valleys, it is less, from 1°.2 to 2°.5. Compared with the average for the same month of last year, the former is the lower for the stations in all of the districts, except the South Atlantic States, Tennessee, and the Ohio Valley, where it varies slightly above and below the latter.

RAIN-FALL.

Map No. 3 gives, approximately, the rain-fall for the various districts east of the Rocky Mountains. A table upon the same shows where there has been the average fall, excess, or deficiency.

RIVERS.

The observations show that the Missouri, Red, Mississippi, and Ohio Rivers fell quite steadily during the month, excepting slight oscillations in the head-waters of the two latter, produced by rains. The Cumberland fluctuated more or less, having been lower October 1 than September 1. Upon map No. 3 will be found a table which explains itself.

Sixty-one cautionary signals were ordered to be displayed at our own stations during the month for seven storms, and the majority of them on the lakes. Thirty Canadian stations were warned of the approach of storms.

PAPER 27.

Special Orders No. 78.

WAR DEPARTMENT, OFFICE OF THE CHIEF SIGNAL-OFFICER, *Washington, D. C., June 14, 1871.*

Sergeant Frederick Meyer, observer, Signal-Service, U. S. A., will proceed without delay to New York City, and report to Captain C. F. Hall, commander of the North Polar Expedition, for duty in connection with that expedition. He will, in addition to the performance of duty under the orders of Captain Hall, carry out the written instructions received from this office.

The Quartermaster's Department will furnish the necessary transportation.

By order of the Chief Signal-Officer of the Army,

GARRICK MALLERY,

Capt. and Bvt. Lieut. Col., U. S. A., Acting Signal-Officer and Assistant.

Digitized by Google

WAR DEPARTMENT, OFFICE OF THE CHIEF SIGNAL-OFFICER,
DIVISION OF TELEGRAMS AND REPORTS FOR THE BENEFIT OF COMMERCE AND AGRICULTURE,
Washington, D. C., June 12, 1871.

SERGEANT: The Chief Signal-Officer directs that you will take daily observations during your entire expedition at 7.35 a. m., 4.35 p. m., and 11.35 p. m., Washington mean time, of the barometer, thermometer, wind, and weather, and such additional meteorological observations as are compatible with the duties assigned you by Captain Hall.

Among these additional observations, you will particularly bear in mind the following:

1. Frequent observations of the barometer, wind, and weather at hours intermediate to the above.
2. Regular observations of the minimum and maximum thermometers.
3. Velocity of wind at sea, especially in gales, and made with numerous anemometers in different positions.
4. Forms and motions of clouds, and meteor-tracks.
5. Ozone.
6. Electrical and auroral phenomena.
7. Solar and terrestrial radiation thermometers.
8. Forms, &c., of snow-crystals.
9. Heights of twilight arcs—noting the time very exactly.
10. Dew-point at very low temperatures.
11. Spectrum-lines or bands in the aurora and the atmosphere.
12. Polarization of atmospheric light and position of neutral points.
13. Rain and snow fall at different altitudes.
14. Temperatures of sea and rivers and springs, and the earth and snow at depths of 3, 6, 12, 24, and 36 inches.
15. Habits of plants and animals as affected by climate.

You will take special care to make accurate comparisons of your barometer, &c., with other instruments that you may find at points on your journey, that have been used for meteorological observations.

You will keep all the records for any period as far as possible in one and the same book; dividing it into two portions, one for the systematic observations at regular hours, the other for occasional observations.

You will keep a duplicate record of the systematic and more important occasional observations on Form 4, and forward the same to this office as often as occasion may offer.

Very respectfully,

H. W. HOWGATE,
Second Lieut. and Bvt. Capt., U. S. A., Acting Signal-Officer and Assistant.

Sergeant F. MEYER,
Observer, Signal-Service, U. S. A.

SERGEANT FREDERICK MEYER'S REPORT ON THE NORTH POLAR EXPEDITION, 1871–'73.

WAR DEPARTMENT, OFFICE OF THE CHIEF SIGNAL-OFFICER,
Washington, D. C., July 1, 1873.

GENERAL: I have the honor to inclose a report of my proceedings while in connection with the North Polar Expedition, which, by Special Order No. 78, I was ordered to accompany. All items and data of this report are from memory, and are based upon notes taken at the time of their occurrence, with the exception of a few observations for geographical position, and general outline of adventures while living on the ice.

The report naturally arranges itself under the two general headings—

I. History of the expedition.
II. Scientific operations of the expedition.

Heading II, according to the instructions of the National Academy of Sciences, consists of—

1. Astronomical observations.
2. Magnetic observations.
3. Observations on the force of gravity
4. Observations on ocean physics.

Digitized by Google

5. Meteorological observations.
6. Natural history.
7. Geology.
8. Observations on glaciers.

No. 1 subdivides—

A. Astronomical observations at winter quarters.
B. Astronomical observations on sea and at ports of Greenland.
C. Astronomical and geodetical observations, forming a series of systematic surveys.

No. 2 subdivides—

A. Differential observations.
B. Observations on absolute declination.
C. Observations on intensity, (relative and absolute.)
D. Magnetic inclination.

No. 4 subdivides—

A. Depths.
B. Examination of sea-bottom.
C. Sea-temperature.
D. Density of sea-water.
E. Currents.
F. Tidal observations.

No. 5 subdivides—

A. Pressure of atmosphere.
B. Temperature.
C. Winds.
D. Clouds.
E. Precipitations.
F. Ozone.
G. Solar and terrestrial radiation.
H. Crystallization of snow.
I. Moisture.
K. Electrical phenomena.
L. Auroral phenomena.
M. Heights of twilight arcs.
N. Optical phenomena.
O. Shooting-stars and meteors.
P. Miscellaneous.

F. MEYER,
Observer Signal-Service, U. S. A.

Brig. Gen. A. J. MYER,
Chief Signal-Officer of the Army.

GENERAL DESCRIPTION OF THE VOYAGE OF THE STEAMER POLARIS FROM NEW YORK TO GODHAVN, DISCO.

I.—HISTORY OF THE EXPEDITION.

In compliance with the instructions received from the Chief Signal-Officer of the Army, I proceeded to New York in order to report myself to Captain Hall, commander of the North Polar Expedition, then about in readiness to leave port on its voyage to the arctic regions. Arrived at New York, I set at once to work to procure several instruments to complete my outfit as meteorologist of the expedition, and arranged my plans in regard to meteorological work.

All this occupied the entire time the Polaris was anchored at the Brooklyn navy-yard, where numbers of visitors appeared every day to look over the ship and give us their wishes to the adventurous enterprise which we were then about to undertake. The noble people of New York and Brooklyn did not only wish us a successful voyage, but they also contributed largely to our library, in presenting, for the use of the crew, enough of reading-matter to wear away agreeably the long and dark winter months soon to come.

Digitized by Google

A few days before we left port, the Geographical Society of New York gave a reception to the officers of the expedition, during which Captain Hall gave a detailed description of the expedition, and his plans in regard to the main object of the voyage—the discovery of the north pole and the tract of land surrounding it. Also Dr. Bessels, the chief of the scientific party of the expedition, expressed his confidence of its success, which should make us more worthy of such honoring reception.

Finally, having completed all preparations for a voyage of such long duration, Captain Hall heaved anchor at 12 o'clock m., June 29, 1871, and proceeded about half a mile up the stream, where he laid to, in order to start out with the tide through Hell-Gate, which he accomplished at 7 p. m. the same day.

The company on board the Polaris consisted of Captain Hall, commander; Mr. Buddington, executive officer and sailing-master; Mr. Chester, first mate; Mr. Morton, second mate; Dr. Bessels, chief of scientific party: F. Meyer, meteorologist; Mr. Schuman, first engineer; one steward; one cook; a crew of twelve firemen and seamen; Joe, Hannah, and Punny, the Esquimaux interpreters. Besides these, Colonel Lupton, of the Patent-Office at Washington, an intimate friend of Captain Hall, who had assisted him for some time in arranging the business in connection with the expedition, accompanied us to New London, so that he might stay with his friend as long as circumstances would permit.

After a very pleasant trip we arrived at New London Harbor the following day, June 30, at 11.30 a. m., where I at once set to work to make arrangements for meteorological observations, to be taken while on the Atlantic, and actually made a series of comparisons of Adie's mercurial marine barometer, No. 767, with Green's mercurial standard barometer, No. 947, and found its error (in comparison with Green's No. 947) to be equal to 0.108.

All instruments were suspended in an instrument-shelter, fifteen inches wide, two and a quarter feet long and four and three-quarters feet high, and fastened to the port side of the pilot-house. They were placed in such manner as to secure as well as possible protection from radiation. The bulbs of the thermometers were about four feet eight inches from the deck of the ship, and two feet from the top of the shelter, six inches from the wall of the pilot-house, and nine inches from the blinds of the shelter. The barometer and ozonometer were also suspended in the instrument-shelter, the anemometer being located nearly half way on the port side of the quarter-deck. The instruments exposed for use were Adie's mercurial marine barometer, No. 767; Green's mercurial thermometer, No. 2893; Green's psygrometer, No. 1822, A and B; Robinson's (Green) anemometer, No. 40; ozonometer, and one Miller Casella's thermometer, to observe maximum and minimum temperature. A rain-gauge could not be properly exposed, and therefore a small one was set up, which could only be used at certain times.

Having everything ready for operation, I commenced to take observations on July 1, at 7.35 a. m. and 4.35 p. m., Washington time, after ascertaining that the elevation of mercury surface in cistern of barometer was equal to 8 feet 9.5 inches.

As on the previous day, people streamed on board the Polaris, looking over the steamer and greeting the explorers.

The main object of going into port at New London was the procurement of a second engineer, which Captain Hall accomplished in securing Mr. Odell for the said position. Toward evening, ladies of Groton Bank visited our vessel, took possession of the cabin and organ therein, enlivening our close quarters with their sweet songs and witty conversation, so that really space seemed to widen and time to rush.

During the succeeding day, July 2, two observations were made at 7.35 a. m. and 4.35 p. m., Washington time. In the afternoon gentlemen and ladies both of New London and Groton Bank rowed over to the Polaris, in order to attend the divine service, which was to take place on board of the vessel at 4 p. m., being held by Revs. Foster and Allen, ministers of New London and Groton Bank. At the appointed time the quarter-deck was entirely taken possession of by our visitors, and the service was opened by Minister Allen, in delivering a prayer and reading the chapter, after which Minister Foster, in a longer sermon, illustrated the dangers of our expedition, the scientific facts which were to be gained, and the laurels which were to be conquered by accomplishing the object of our expedition in reaching the north pole.

After the final prayer, the gentle people of New London and Groton Bank returned to their homes, bidding us good-by over and over again, and wishing us success, which they had the confidence would meet us.

On the following day, at 4.20 a. m., we left New London Harbor on the way to St. John's, Newfoundland, and as soon as we had cleared the Harbor, Colonel Lupton and the pilot left the vessel under the cheers of our officers and crew. We had fair weather until 10 a. m., when a heavy fog set in, and the sea commenced to swell considerably. Navigators and seamen on the portion of the Atlantic in which we were cruising, seeing a heavy fog always followed by a swell of the sea, explain one to be the cause of the other, while really both phenomena appear to me to have their origin in the same cause.

Digitized by Google

From north latitude 40° and west longitude 70° to north latitude 42° 20′ and west longitude 60°, the equatorial and polar currents follow their course respectively, east-northeast and west-southwest, in close proximity, and produce heavy fog by rapid change of temperature of air-currents as they pass over the surface of sea-currents of such different temperature. On the other hand, whenever the wind blows in such direction as to cross sea-currents, driving the waters of one into the other, the different specific gravity of those currents will necessarily cause an additional motion of the waters, which is shown by the above-mentioned swell.

At one hour, Greenwich time, we commenced to take three-hourly meteorological observations, which, in connection with the latitude and longitude derived from astronomical observations and the log, make up the complete meteorological record of the voyage. During the following day, the fog and swell of sea continued to increase, showing a clear sky whenever the fog was depressed by a strong upper current.

Also on July 5 and 6, we were perfectly encircled by a fog, the sea continuing to be high.

Early on July 7 having come up to north latitude 42° 20′ and west longitude 60°, the fog disappeared, and the sea ran smooth.

On July 5 we commenced to take frequent observations of the sea-temperature on the surface and at greater depths, as also of the specific gravity of the water. In the evening the sea-temperature fell very rapidly, we being far from the direct influence of the equatorial current.

During July 8 fog made its appearance again, the wind blowing from a westerly direction which carried the warmer air over the cold currents, upon which we were then progressing. and which kept a nearly stationary temperature.

On July 9 the temperature of the sea fell still more, governing the temperature of the air, while heavy fog, caused by northerly and westerly wind, would not permit us to run the ship during night on such dangerous grounds as the Newfoundland banks.

Toward morning of July 10 the fog condensed into light rain, until in the afternoon when the sea-temperature suffered a very rapid depression, which caused heavy fog, going over into rain.

Finally, at 12 m., July 12, we arrived at St. John's Harbor, where we found the sea-temperature quite low, while the air-temperature, influenced by the soil, was considerably higher. Hardly any fog makes its appearance in St. John's Harbor, the air being very dry, and not capable of producing condensed vapor in the lower strata of atmosphere.

St. John's Harbor forms a small basin encircled by granite rocks, having the appearance of being encaved and rounded by former glaciers. We anchored at St. John's Harbor until the 19th of July, Captain Hall being engaged in making additional purchases of coal and provisions. At 4 p. m. July 19 we left St. John's Harbor, being accompanied by the American consul of St. John's, who, when he left the ship with the pilot, was cheered three times, to which he responded in the same manner.

About five miles from the coast, bearing southwest by south, we saw a mirage of a peninsula, showing an inverted image immediately above the one seen directly and in most distinct outlines. We also saw a faint aurora at 9 p. m. of 45° altitude bearing due north, and consisting of faint red and yellowish rays going over into white light.

On July 21 we found the sea-temperature increasing and nearly equal to that of the air. Toward morning of July 24, north latitude 55° 42′ and west longitude 51° 30′, the sea-temperature stood above that of the air until morning of July 25, when the air-temperature rose above that of the sea.

On July 25 toward midnight we saw a brilliant aurora, which, making its first appearance as an illuminated cumulo-stratus cloud, soon transformed into a broad ribbon of a square-edged, screw-like appearance, and based by the same cloud, which showed a yellowish light. The ribbon or screw showed distinctly all colors of the spectrum, and spreading parallel with the horizon, and at the crown, first formed a faint arc of spectrum light over its crown and then transformed itself into a faint arc of spectrum light, which finally combined with the upper arc, showing a most brilliant arc of spectrum light with diverging rays of purple and violet color.

On July 27 we arrived at Fiskenaes, where Captain Hall intended to engage for the service of the expedition the Esquimaux, Hans Christian, who had been a member of the expeditions under Dr. Kane and Dr. Hayes.

We were informed that Hans Christian was then at Upernavik, and in the Danish service. Fiskenaes is a small village of seventy inhabitants, which are mostly half-breed Esquimaux, and live on the earnings of seal-hunting and fishing, by exchanging them for provisions and necessaries of life which the Danish government provides for them. This exchange is conducted by Gov. M. Shonheyder, under whose jurisdiction comes also the little missionary settlements of Lichtenfels, located on the same island to the southwest, and inhabited by ninety members of the brotherhood. Both villages belong to the district of South Greenland, and their provisions are sent yearly in open boats from Godhaab, the principal place of South Greenland, which boats return to Godhaab with the fat, blubber, and cod-livers bought by the governor of Fiskenaes.

Digitized by Google

Fiskenaes is entirely built on rocks, which consist of granite, with quartz-veins and porphyry. Vegetation is scarce; only the governor possesses a few artificial beds of vegetables, but an abundance of alp-flora are vegetating in the neighborhood. Very few reindeer are to be found near Fiskenaes, and the ice-bear approaches only about once in twenty years; but an abundance of seal and codfish is yearly collected.

The Esquimaux inhabitants are of good appearance, well fed and healthy-looking, which the governor assures me is the result of a law issued by the Danish government prohibiting the sale of fresh fish and compelling the natives to keep a large supply of fish on hand in storage for the long cold winter.

The male Esquimaux, in average, measures five feet, is of rather lazy habits but great endurance, and from eight to fifteen live in one small house built of lumber, and covered with peat, or entirely built of turf. The female Esquimaux is smaller but with very small hands and feet, and their hair tied at the crown of their heads by a ribbon, which, according to its color, signifies their state in relation to matrimonial life. A red ribbon signifies the female to be a virgin; blue, a married woman; black and white, a widow; white with a small ribbon wound around it, a widow who wishes to marry; green, a girl who has borne a child.

Each congregation has a teacher or cathecet, who preaches the divine word, but is not allowed to join members of the congregation in matrimony.

The minister of the gospel and physician visit the place once a year.

Several remarkable habits of the Esquimaux were related to me, of which I note the following most remarkable:

After taking the holy sacrament each native shakes hands with all present Europeans, which signifies their gratitude in regard to the acquirement of the Christian religion. Mortality among the natives is not great, but greatest in spring. It has been related to me that during last winter forty inhabitants of an island near Julianhaab perished by starvation, being blocked in by ice in such a manner as not to permit any provisions to be sent there.

The mean temperature of Fiskenaes during summer months is said to be about +1° Reaumur, while the winter is not very severe, and sometimes rather mild, as in the case of the preceding one, when the greatest cold observed was —14° Reaumur. The prevailing winds are northerly in winter and southeasterly in summer.

During winter months a southeast wind bears almost always the character of a gale approaching in elastic waves, which strike the lower strata of the atmosphere at intervals, and are very dry and rather mild. The snow-line in South Greenland, I was informed, varies from 2,000 to 3,000 feet elevation, and therefore no permanent snow is known at Fiskenaes, none of the surrounding mountains being higher than 2,000 feet.

At 3 a. m., July 29, we left Fiskenaes, encountering a southwest gale, indicated by a light westerly wind and a rapid rise of the barometer on the evening of the preceding day and morning of July 29. At 8 a. m. the wind veered to northwest, the barometer falling rapidly, which continued after the wind had veered to southwest.

The change of wind to southwest was accompanied by light rain, which ceasing at intervals grew into heavy rain, with an increasing force of wind.

At 7 p. m. the maximum velocity of wind was thirty-six miles per hour, and the minimum height of the barometer was 29.049, occurring at 8 p. m., when the force of wind gradually decreased, and the barometer slowly rose until 11 p. m.

At 11 p. m. the wind shifted slowly to west on the way to northwest, and rapidly lessened its force—the barometer rising rapidly, and clouds clearing away.

During the entire time the thermometer, within a very small range, marked distinctly the succeeding phases of the storm, rising until the barometer reached its maximum, on the morning of July 29, and then falling up to the time when the southwest wind set in, when, rising again for a short period, it continued to fall until the wind gradually veered to west. At 11 a. m., July 31, we arrived at Holsteinborg, where we found two Swedish government vessels, (steamer and schooner,) which were then on their return to Sweden, having been sent to Disco, in order to take up a piece of meteoric iron, which is thought to weigh about 300 tons, and in addition to which they found two more pieces of the same structure. These two vessels, under command of Captain Van Otter, having on board a botanist and a geologist, steamed and sailed up as far as Upernavik, sounding and ascertaining frequently the surface and bottom temperature of the sea. They also stated that the sea upon which they had been cruising was unusually free of ice, and very favorable for our voyage.

At 4 p. m., August 2, the Swedish vessels left port, proceeding on their voyage to Sweden. Holsteinborg is a small but beautifully situated village, surrounded by high and steep mountains of granite, and under the jurisdiction of Governor Elsborg. Barren of vegetation, with the exception of a few artificial beds of vegetables in possession of the governor, the alp-flora is of less variety. Reindeer are scarce, and when we reached Holsteinborg no reindeer-skins were to be got—ice-bear being also a rarity.

The natives are of the same type as at Fiskenaes, following the occupation of hunting

Digitized by Google

and fishing, and occasionally whaling, which they keep up with success on their own coast during winter, sailing to the west side of Davis's strait during summer.

On July 31, Captain Hall, Dr. Bessels, and I went ashore, in order to take sights for longitude of Holsteinborg, and ascertained, according to my computation, Holsteinborg to be situated at 53° 53′ 45″ west longitude.

At 3 p. m., August 3, we left Holsteinborg, and proceeded to Godhavn, or Lively, Disco.

About thirteen miles from Holsteinborg we passed by the peak known as Woman's Hood, which on its southerly extremity resembles very much a woman's hood, and of which I made a sketch. We arrived at Godhavn at 3 p. m. August 4, where, in consultation with the governor of Lively, Mr. Lassen, we learned that good coal might be got at Scansen and Rittenbank, but that the first-mentioned place was dangerous to anchor at, being exposed to southwest gales. Captain Hall, therefore, concluded to wait for the supply-vessel until the 15th of August, and then proceed to either one of these coal-mines.

He also dispatched a boat, under the command of Mr. Chester, to Jacobshavn, where the inspector of North Greenland stopped at the time, in order to induce him to come to Lively, so that Captain Hall might be able to procure the necessary stores, in case the supply-vessel should not arrive in time. Mr. Chester left Godhavn at 1 p. m., August 6, and returned at 2.30 a. m., August 11, bringing with him specimens of the coal of Scansen, which showed the structure of wood, and formed thin layers.

On August 5 we saw a parhelion, which showed a distinct eccentric ring of spectrum colors, the red light facing the sun; yellow, green, and faint blue following in succession. The altitude of the sun was at the time 14° 54′, and of the ring (vertex) 75° 26′. Bearing north of the sun at a distance of 22° 42′ a parhelion made its appearance showing faintly the spectrum colors, the red light facing the sun, yellow following, and ending in distinct white rays of at least 20° length.

On August 10, at 2 p. m., the steamer Congress, under command of Captain Davenport, with supplies of provisions and coal, arrived at the port, having on board Dr. Newman and Mr. Bryan, ministers of the gospel, and Mr. Bryan, jr., the astronomer of the expedition.

I will briefly state that after the arrival at Godhavn of the Congress, with provisions and coal, several days sufficed for the transfer of these provisions and coal, partly to the Polaris and partly to the store-house of the Danish government. While at this locality Captain Hall was considering about my return to the United States; he had ordered me solely to attend to the navigation of the vessel and keeping of his journal, and prohibited all meteorological observations, and observations of any description; this order I thought to be in discordance with my instructions and the general purpose of my presence with the expedition, and I therefore applied for permission to return to the States. At first Captain Hall appeared willing to grant my request, but shortly before the Polaris left Godhavn he changed his intentions, and permitted me to comply with my instructions from the office of the Chief Signal-Officer of the Army, besides the execution of his own orders. I gladly accepted Captain Hall's decision, and expressed my general willingness to promptly execute his orders.

Leaving Godhavn, where Captain Hall had procured a written permit of the inspector of North Greenland for Hans, the Esquimaux, to leave the Danish service, and enter that of the Polar Expedition, the Polaris headed to the west of north, and after two days' run arrived at Upernavik, a comparatively large settlement of natives, under the Danish government. At the latitude of Upernavik, and even farther south, the coast of Greenland is studded with small islands and rocks, which like a line of skirmishers protect the coast from the wearing influence of the heavy arctic ice, continually grinding by on its long trip from the high northern latitudes, where it arises and grows, to the Atlantic Ocean, where it wastes and finally disappears. On one of these islands Upernavik is situated, with a snug little harbor, protected on three sides by hills of respectable size. As soon as the anchor dropped, Dr. Rudolph, the governor, and Mr. Elberg, who was to take the governor's place in the course of a few days, visited the Polaris, and at once were presented by Captain Hall with letters from Inspector Smith, who enjoined the Danish officers to do their utmost in procuring dogs and skins for the expedition, as well as to be of general assistance to Captain Hall in the business transactions of the expedition. Already, the morning following our arrival at Upernavik, a great number of seal and dog-skins and a few dogs were received on board, and a boat expedition under command of H. C. Chester, mate, sent to Proven, to the governor of which Dr. Rudolph previously had dispatched, by kiak-mail, orders for Hans's departure from Proven, and for the deliverance of the same to Mr. Chester, who was ordered by Captain Hall to engage Hans's services for the expedition. Mr. Chester with Hans and family returned to the vessel a day or two after. Soon after the Polaris was gotten ready for departure, and the governor, Mr. Elberg, who had succeeded Dr. Rudolph, accompanied the expedition to Tessuisak, where he intended to assist Captain Hall in procuring a great number of dogs, and to conduct the final business transactions of the Danish government with the North Pole Expedition.

Digitized by Google

Tessuisak is situated on an island which lies in the entrance of a deep bay, the head of which consists of a large glacier, and consequently the bay always abounds in icebergs. At the season of our stay at Tessuisak these icebergs were rather far advanced in decay, and hardly at any time the air would not be vibrating by the tumbling and rolling of one or the other iceberg, causing a noise most similar to the sounds of battle in the roaring of field-pieces.

As expected, Captain Hall procured a number of dogs and ready-made skin clothing at Tessuisak, settled his accounts with the Danish government, and, as soon as the weather permitted, left the harbor of Tessuisak with Mr. Jensen, the acting governor of Tessuisak, as pilot. Captain Hall had exerted all his powers of persuasion to induce Mr. Jensen to join the expedition, but in vain. Mr. Jensen would only agree under the unreasonable condition that he should have the command of the vessel on her arrival in Smith's Sound. The first evening and night after leaving Tessuisak we made but little progress in Melville Bay, as thick fog compelled us to advance carefully: but on the morning of the second day Cape York was sighted and the appearance of Cape Dudley Digges expected. When arrived at the latitude of Cape Dudley Digges, it was found impossible to land and comply with the instructions of the Secretary of the Navy, as heavy ice intervened between the vessel and the shore. Running close to the coast, we passed Wolstenholm Sound, between Wolstenholm Island and Cape Athol, and leaving the latter on the starboard quarter we ran up to within five or ten miles of Fitzclarence Rock, where the vessel had her first trial of working ice, in pushing through it from Fitzclarence Rock to Cape Parry, at the latter, where she entered the open water again by holding more to the westward. Passing Northumberland Island at a considerable distance west, the Polaris without difficulty ran up to within a few miles of Cape Alexander, and leaving at her stern in succession Port Foulke and Renselaer Harbor, the winter-quarters of Dr. Hayes and Dr. Kane, she crossed Smith's Sound and came within a few miles of Cape Hawks, where she encountered ice, but we rounded it by steering south and west; then running parallel with the coast until we arrived opposite Cape Frazer, she was stopped, and Captain Hall, accompanied by Mr. Tyson, inspected the little inlet to the north of Cape Frazer for its qualification as either provision-depot or winter harbor; but finding it shoal, Captain Hall abandoned all ideas of establishing his winter-quarters at the locality, and also failed to establish a depot. Keeping within ten or fifteen miles of the coast, we ran up Kennedy Channel, winding through more or less ice, until, in a thick fog, an ice-barrier appeared to stretch across the channel. After several fruitless attempts, an opening was discovered, which led us to within two miles of an island seen on our starboard bow. Five or six hours later we found Kennedy Channel to be widening, and at about 9 a. m. Captain Hall and myself made observations for longitude, which, computed separately, determined the latter to be 64° 35′ west, (if my memory is not in error.) The fog shutting in, the vessel was stopped, until at 12 m. all persons capable of making observations for latitude agreed our latitude to be 81° 24′ north.

At 1 p. m. the sky and horizon cleared, the vessel started, and then we saw, in place of Kane's open Polar Sea, a long stretch of coast-line to the east of us, which, bare of snow, sweeped in a shallow curve from north to south; the west side of the channel was also in sight, the general character of the land being torn and weather-beaten rocks, with mounds of loose rocks and gravel in front of them. Steaming parallel to the east side of the channel, we, toward evening, entered a still narrower strait, which received the name of Robeson Channel, called so by Captain Hall after the Honorable Secretary of the Navy. On we proceeded in this channel, passed a deep bay—afterwards called Newman's Bay—until hauled up a second time by an ice-barrier, when Captain Hall ordered the vessel to be fastened to a floe, while I was busy computing the dead-reckoning from our last observation—81° 24′ north, 64° 35′ west—to the present position of the ship. I was then invited to Captain Hall's room, and telling him the latitude, 82° 16′ north, and longitude, which I cannot recall, found, by dead-reckoning, also temperature of atmosphere and surface-water, pressure of atmosphere, &c., he filled out two of the printed forms of records with a short extract of the expedition's history, position of the vessel, data of weather and sea, and a statement of the ice prospects of still advancing further north. One of these records Captain Hall inclosed air-tight, in a copper cylinder, previously weighted on one end with shot, and retained the second copy. Only a short time the vessel remained fastened to the floe, when she was directed to the east and south, until we arrived at the east coast, near a small inlet. Here Captain Hall and Mr. Tyson visited the inlet, and examined it as to its qualification as a harbor, but found a strong action of the tide and ice working. The vessel then steered back to the westward, and fastened to a floe, where she remained all night. Early next morning the vessel returned to the above-mentioned inlet. Captain Hall and Mr. Tyson re-examined it; but finding their opinion of the previous day corroborated, Captain Hall called a council of the ship's officers to decide upon the further course of the vessel, and enjoined me to record the proceedings of the council. During this council all the officers, with the exception of Captain Buddington, expressed the same opinion, according to which the vessel should be directed north

Digitized by Google

and west, endeavoring to find a lead north, and, if not successful, to make the west coast and a harbor thereon. Captain Buddington's opinion was to enter the above-mentioned inlet, afterwards called Repulse Harbor by Captain Hall, and establish winter quarters; or, if not disposed to do so, to run south to what afterwards was called the Southern Fjiord, and anchor behind the island at its entrance. Captain Hall decided in favor of the majority, and the vessel slowly worked through ice on a course a little to the north of west, but instead of gaining lost ground in latitude. Finally, fog shut in, she was fastened to a floe, and soon got beset by heavy ice. In this condition she remained four days, during which time she continually drifted to the southwest. While beset, the vessel at times would labor under such heavy pressure that Captain Hall twice thought it necessary to deposit stores and provisions on the floe. On the evening of the fourth day of drift the ice spread, and the Polaris steamed on a nearly due east course to the shore and anchored in a shallow inlet, which received the name Thank God Harbor, called so by Captain Hall. This inlet could hardly be called a harbor, and the only protection against the grinding ice the Polaris found, was a large grounded iceberg, to which Captain Hall gave the name of Providence Iceberg. Next morning stores and provisions were landed, and the determination of latitude and longitude was commenced by Captain Hall, Mr. Bryan, and myself.

A few days after our arrival at Thank God Harbor, Captain Hall enjoined me to at once survey it, which I executed by surveying from the southeast cape of Robeson Channel, called Cape Lupton by Captain Hall, to the northeast cape of the Southern Fjiord. Thank God Harbor is formed by low, sandy land, which evidently is an alluvion from the hills to the northeast of it. These hills vary from 900 to 1,300 feet in height, are of slate formation and very much torn and weather-beaten, but bare of snow in summer. The water of the harbor is shallow—fourteen or fifteen fathoms being the average depth.

On our arrival at Thank God Harbor we found it thickly populated by geese and ducks, but they were missing next morning. While engaged at the survey of Thank God Harbor I met with two accidents which nearly terminated my earthly existence.

One morning, going out with the intention of stationing myself on the summit of the hill north of the vessel, deeply in thought, I took the wrong route and soon found myself on an almost perpendicular portion of the hill; endeavoring to climb up I lost my foot-hold, and was precipitated down a height of at least 200 feet; a heavy stone rolling down behind me caught my coat and stopped my involuntary descent, saving me from finally bringing up against a rock. At another time, in company of Mr. Bryan and Mauch, I crossed Polaris Bay to its south coast on the newly-formed young ice, and when returning Mr. Bryan and myself in succession fell through a crack, and were only saved from being drowned by rendering assistance to each other; and from freezing to death, by keeping on a sharp pace until our arrival at the ship, when Mr. Bryan, almost entirely used up and insensible, had to retire to bed immediately. Mauch had stayed back, and when finally arrived at the vessel he was staggering, out of his senses, and hardly able to keep himself up.

Soon after, Captain Hall sent out a sledge journey under command of Mr. Chester and accompanied by Dr. Bessels; this expedition traveled about fifteen miles south, and from the range of hills on the south coast of Polaris Bay saw a glacier extending east and west as far as eye could reach; they also found an elevated plain bearing to the northeast, between the range of hills northeast of Thank God Harbor, and those at the south coast of Polaris Bay, and shot a musk-ox. Captain Hall now prepared for a sledge journey, but was not quite ready until the 10th of October, when he issued orders to Captain Buddington and Mr. Morton in reference to the command of the vessel and provision matters, and started with two sledges, accompanied by Mr. Chester, Joe and Hans, with the intention of a two weeks' absence. The object of this journey was to reconnoiter the land as to its qualification as a route to be taken in spring, and to get acquainted with the resources of the country. During the absence of Captain Hall, the observatory was erected and fitted out; when he returned, on the 24th of October, 1871, we were ready to commence all observations prescribed by the instructions of the National Academy of Sciences.

From what I learned afterward, Captain Hall had been to Newman's Bay by way of the elevated plain mentioned above, and traveling to the entrance of Newman's Bay, ascended the cape, on the northeast, and deposited a record at the summit of said cape.

Soon after Captain Hall had set foot upon the vessel he was taken ill, complaining of the stomach, and retired to bed; next morning his left side was found paralyzed, and he remained in this state for some days, when he became better, left his bed, walking about in the cabin, and having his secretary, Mauch, read to him; he then had a relapse, took to the bed again, and became delirious, in which state he remained until the 8th of November, 1871, when he died. The remains of Captain Hall are interred at about half a mile to the southeast of the ship's anchorage; the place of interment was marked by a flag, the solidity of the frozen ground not permitting the erection of a board until the spring following. The engraving upon the board gives the principal achievements of the expedition, the age of Captain Hall, and date of his death and burial. During

Digitized by Google

the summer of 1872, I included Captain Hall's grave in the general survey of Thank God Harbor, by reference to three points previously determined by the theodolite and chain.

After Captain Hall's death, Captain Buddington assumed command of the vessel and jointly with Dr. Bessels issued a proclamation, wherein they stated that the provisions made by the Secretary of the Navy, in case of Captain Hall's death, should be carried out; that Captain Buddington would have the command of the vessel, while Dr. Bessels was to direct all sledge journeys and scientific operations. Arctic night had then set in, and scientific observations at winter-quarters had commenced; the vessel had been housed in under canvass and banked in with snow. During the entire Arctic winter, the members of the scientific party were busily engaged in carrying out the instructions of the National Academy of Sciences, while all others had to content themselves with active exercise on the ice and the reading of books of instruction and fiction. No marked incident or accident occurred during the four and a half months' darkness, with the exception of one soon after Captain Hall's death. During a severe northeast storm, the ice, wherein the Polaris had bedded, broke up, the anchor-chain, also frozen in, was carried with the ice, and the anchor dragged; it therefore was found necessary to unshackle the chain, and the Polaris drifted to the southwest, bringing up against Providence Iceberg, to which she was secured by ice-anchors. The northeast storm, the original cause of this accident, lasted three days, and had commenced two days before the vessel broke out; it started as a high wind during my watch at the observatory, and increased to a tremendous gale during Dr. Bessel's watch.

Waking up in the morning, I found the vessel laboring heavily, and from different sides heard fears expressed of Dr. Bessels's safety. I therefore got a few victuals to take with me, and left the vessel; but struck by the gale, I found it impossible to stand up, but had to be content with making my advances on all-fours. Dark as it was, the snow drifting so as to enter through clothing and lodge near the skin, I could not see but one yard ahead of me; and if, by inclining my shoulder too much either left or right, I once took a wrong direction, it was more than likely that I never would see again either observatory or ship. Steadily I advanced, and soon had the satisfaction to arrive at a pole, erected in line with the observatory and ship, close to the beach. I now endeavored to crawl up the ridge to the observatory, but was driven back by the wind a number of times, until finally I succeeded in getting under the lee of the provision-depot, and from there to the observatory. I found Dr. Bessels suffering with the cold, (—28°,) and anxiously waiting for an opportunity to return to the vessel. He had made several attempts to return, but the fearful tempest had defeated his physical strength. He had registered the meteorological features of the storm that a light could not be kept burning any longer, the wind blowing at the rate of from eight miles per hour, and still increasing.

Soon after my arrival at the observatory the two natives entered, having followed me, but lost their route. We then all started for the vessel by sliding on the ice, driven by the wind; when the ship loomed up we were within a few yards of it; all arrived safely at the Polaris without injury, excepting a few slight frost-burns.

Soon after the northeast gale's abatement a southwest storm sprung up, which by driving the iceberg inshore, caused a heavy pressure on the vessel, so much so that Hans and family sought refuge at the observatory. During the entire winter the vessel had a list to starboard, and thereby strained her stern and bows, which were found to be in a leaky condition as soon as the ice around the vessel commenced to melt.

On the 28th of February, 1872, the sun made his re-appearance, but was then near 2° high at 12 m. I never before saw such enthusiasm and rejoicing over a sunrise as on that occasion; and I especially recall the carpenter, who during the winter had shown symptoms of insanity, carrying around a bottle of claret, which he had preserved during the entire winter, and inviting everybody to drink with him. And, indeed, the sun's rise, after four and a half months' absence, was a matter to rejoice in. I think everybody had felt the influence of the absence of light by losing appetite, sleeplessness, and depressed spirits.

Dr. Bessels now officially communicated with Captain Buddington, making the following propositions: As soon as daylight is sufficient, to start two different sledging parties, one north and the other south; the southern expedition to connect our station with Cape Constitution, and to consist of one sled; the northern expedition to proceed on the strait ice, with two sleds, and to make land, if possible, north of Polaris Bay, and to proceed from there either along shore or on land farther north; the vessel as soon as broken out, to make her way in the same direction, and come to the relief of the northern expedition. These propositions were rejected by Captain Buddington in an official communication, stating that as soon as small leads occurred he would start to the north in two boats. This decided the question, and we all were anxiously waiting for the occurrence of those leads.

Early in spring the natives and Mr. Chester made several hunting-trips on sledge

Digitized by Google

) Newman's Bay, and always returned, sledges loaded up with meat, leaving the great-
t part stored at Newman's Bay.
Dr Bessels, Mr. Bryan, Joe, and Hans traveled south, crossed the Southern Fjiord,
d proceeding from there about forty miles farther south, Hans recognized Cape Con-
itution at some distance south. A wide crack in the ice stopped the party from vis-
ng the point itself; while in the Southern Fjiord to some distance they saw no head
it, and treasured a great number of important fossils at the island in the entrance of
e fjiord.
About this time I undertook a journey to Newman's Bay for surveying purposes.
ewman's Bay is about forty miles deep, and from seven to twelve miles wide, with
ll-ranges on either side of the entrance and head. In the middle of its length it is
und by an elevated plain on the west side, and by plains, in terraces, on the east side.
these terraces I traveled to about latitude 82° 09′ north, longitude 57° west, and
rveyed as far as the eye could reach. I was stopped by want of provisions, which had
en provided by Captain Buddington.
n June water was making around Cape Lupton, and Mr. Chester, returning from
connoitering, reported in favor of the dispatch of two boats, which were sledged to
pe Lupton, and placed under command, respectively, of Mr. Chester and Captain
son. Dr. Bessels accompanied Mr. Tyson, and I accompanied Mr. Chester. The
rning following our arrival at Cape Lupton, Mr. Chester took to the water, and by
ring and driving over the ice the boat and provisions, we succeeded in reaching a
nt on the coast three or four miles north-northwest of Cape Lupton. Here we
led the boat up on the ice, and a watch was set. The men laid down in a tent,
ile Mr. Chester and myself slept about five yards from the tent and boat.
Early in the morning next day we were roused by the man on watch, who first
orted that water was making round us, and then that an iceberg, propelled by a
vy floe, was coming upon us; but before he had finished his report the ice broke
ween the ice-hook holding the boat, and the boat started to drift; the man on
tch leaped the crack and returned to the boat, then in danger of capsizing with the
and laboring under a heavy strain from the rope holding it to the ice-hook. The
e had to be parted; the boat and tent drifted off with the crew, while Mr. Chester
myself remained near shore on the remainder of the original piece of ice, which
a was crushed by another and heavier piece rising to a vertical position and fall-
down on the former; we narrowly escaped to the shore-ice. A similar fate awaited
piece with the boat and tent on, and when this occurred the crew was just in time
each the shore-ice. I then saw that the boat, although crushed, was partly held
by the ice underneath. I at once leaped over to her, having asked to be warned of
roll or motion of the intervening small ice. Most of the crew followed, and we
eeded in saving part of our clothing, some provisions, and nearly all instruments.
eral times the ice started to roll, and some of us came very near being crushed by
ice. We then returned to the vessel, and on passing Cape Lupton found Captain
on had not started yet.
r. Chester procured permission from Captain Buddington to make a second attempt
the canvas boat, and in the course of a few days we were ready, and sledded the
to Cape Lupton, where we immediately took to the water, pulled a few miles, but
ly were compelled to haul up on a big floe. A heavy north breeze sprung up; the
-ice closed around us and intervened between floe and shore. Here we remained
ntire night, drifting rapidly south, and convinced that, if the ice kept closing in
is, we would have to stay on the floe and finally fall victims of starvation. I
avored to cheer my comrades, but without avail. Thinking this a second failure,
spirits were depressed; nevertheless, we laid down on the ice and slept until
ning, when the ice spread, and we at once launched the boat in the midst of this
nd during the following twelve hours made our way to Newman's Bay, where we
d Captain Tyson, having pulled up his boat on the bay-ice. As no further pro-
could be made, heavy pack stretching across the channel from Newman's Bay to
vest coast, we also took up our quarters on the bay-ice, and remained there during
ollowing six weeks, patiently waiting for an opening to the north.
most every day, while on this stationary bay-ice, I would observe that with the
streak of water would form between bay-ice and strait-ice, extending in a semi-
from Cape Brevoort to Sumner Headland. We have to be thankful for many
ow escapes while on this bay-ice. I will only mention two cases, which occurred
most the same time to each boat, separately. At midnight of some day in the first
of July, the heavy strait-ice closed in upon the bay-ice with such a heavy pres-
that it rose vertically alongside of us, and we were compelled to desert skins,
apidly remove boat and stores, while most of us had no time to protect our feet
ther stockings or boots. During the same night a part of the bay-ice, from which
ain Tyson and boat had removed the preceding afternoon, was crushed to splinters
e grinding strait-ice. I have often wondered how careless the adventurer will
ne when once used to dangers. Similarly to the inhabitant of a large city, who in
of fire will not think of his own safety until the walls of his residence have

Digitized by Google

caught the flames, the arctic traveler, hearing a constant cracking directly under himself, will not stir until he actually sees the ice breaking.

During my stay at Newman's Bay I crossed the bay-ice, and, ascending the northern coast of the bay, traveled on the east shore of the channel until I reached the southern limit of Repulse Harbor, where I staid four hours, in order to determine land and longitude, and to take bearings of all land visible. The station I had selected elevated somewhat above 1,700 feet, and the horizon, at such an elevation, forty miles distant, from north to east-northeast appeared as a continuous bright line dark blue, glittering in the sunlight. Although seen by other observers, and decided to be land, I cannot but announce this bright line to be a sure sign of an open sea. elevations were seen; and if there is any land to the north and east-northeast Repulse Harbor it cannot but be at a considerable distance from where I was viewing the surroundings. The space between this bright line and place of observation filled with smooth cakes of ice, with serpentine leads of water between them. I started homeward, under the impression that any strongly-built steamer, when once fairly through the ice, barring the narrowest part of Robeson Channel, might at full speed run up to this bright line and there find open water for further progress. I had very difficulty in finding our boat among the hummocky ice, and when finally arrived became snow-blind and remained so for several days.

The question may arise, why I did not proceed farther north while traveling shore. In answer, I have to state that, while at Newman's Bay, we from day to day expected an opportunity to start north by boats, and therefore I did not want to be away from the boat longer than twenty-four hours.

In the first part of July, still hoping for success, we got rather low in provisions and two of our crew volunteered to travel over land to the ship and return to us additional provisions. They did so; and soon after Hans, with a note from Captain Buddington, appeared at our encampment, and returned to the ship with Dr. Bessels. Captain Buddington's note requested our presence at the vessel, and ordered Messrs. Chester and Tyson to return to the ship with boats and crew. In answer, Hans bore a note to Captain Buddington, wherein Mr. Chester stated that at present they would not permit a return of the boats. A few days later our two men returned with provisions, stating that the vessel had broken out in June, was very leaky, and that Captain Buddington wanted our presence, so as to enable him to pump the vessel by hand. They also related that Captain Buddington had made several fruitless attempts to take the Polaris up to Newman's Bay for the relief of the boats, and that the vessel was under anchor at Thank God Harbor. At these tidings Captain Tyson, with the assistance of the two boat's companies, excepting Mr. Chester, who staid with our boat, dragged his boat and provisions to the southwest shore of the bay and secured it in a low land, surrounded by hills and the mouth of a deep and serpentine ravine. this season a torrent, which I think is identical with the river mentioned in Captain Hall's dispatch. Captain Tyson and his boat's crew returned to the vessel overland, while Mr. Chester and company staid, waiting for an opportunity to go either north or south in the boat.

About the middle of July a heavy southwest gale set in, and if we had not departed from our encampment before the high wind increased to a gale we undoubtedly would have been crushed. Mr. Chester, with the boat and crew, at once started for shore. I shall never forget that day; I thought it the hardest of my life, until later on our ice-drift. The canvas-boat, mounted on runners, we would push against the storm, which was strong enough to lift boat and all, and in spite of our exertions to the contrary would carry us backward with the boat. We took the boat apart, so as to offer less surface to the wind; we partly unloaded the sleigh by depositing our clothes-bags and some provisions on the ice; but before we succeeded in reaching shore the bay-ice broke up, and we had to continue our work over drift-pieces and wide cracks of water. Finally we got the boat close to shore, and all hands returned in search of the stores deposited on the ice. By partly swimming across floes we succeeded in finding the deposit, and loading ourselves with some fifty to sixty five pounds each, returned in the same manner, arriving safely on shore, while the boat remained on the ice. We hardly had set foot on shore, at Captain Tyson's depot, when the gale increased still more, the ice left shore altogether, and a removal of the boat to shore was impossible. We erected the tent belonging to Captain Tyson's party, which shortly after it blew down, and we sought shelter in the boat of Captain Tyson. Even with the heavy load of provisions, clothing, instruments, and six men, the boat was to be lifted up by the wind, and rolling on the beach, knocking against rocks so as to break her skin in several places. We therefore capsized her, and putting a small load her loaded her down with heavy stones, and passed the night without protection against the fearful gale. Two days later we all returned overland to the vessel, with the exception of one man, and Mr. Chester, who staid with the intention of taking the canvas-boat back to shore as soon as the ice would return to the beach. When I started for the vessel the hills were bare of snow, with the exception of small patches in the shaded corners of ravines; but when about half way, a snow-storm set

Digitized by Google

n and compelled me to take up night quarters in the lee of a small rock. Next morn-
ng it cleared up, and I readily found my way to the Polaris. The vessel was fastened
o a heavy piece of ice; had, during my absence, narrowly escaped from being crushed
y Providence Iceberg falling in; had been aground a number of times, pressed up by
he ice, and was said to be in a very leaky condition.

Captain Buddington intended to direct the vessel south as soon as a lead would occur.
'his took place on the 12th of August; the same day little Francis Polaris, son of Hans
hristian, was born on board the vessel. The Polaris steered west, working through
lack ice, then rounding heavy pack to the north she entered a lead which permitted
er to keep at full speed until next morning, when she brought up against a barrier of
e in Kennedy Channel, to the north of the small island on the west coast, in about
titude 80° 40′ north. Having drifted past the small island, we from 10 p. m. August
3 to 6 a. m. August 14 pressed through heavy pack. At 12 m. of the latter day we again
arted, and making a good progress at full speed of steam we passed by what both Mr.
orton and Hans declared to be Cape Constitution, in about latitude 80° 27′. Cape
onstitution exhibits a peculiar form, and will serve as a landmark not easily forgotten
en by the poorest memory, and I am convinced that Mr. Morton and Hans are per-
ctly sure that what they declared to be Cape Constitution, really is the place named
by Dr. Kane.

At midnight, August 14–15, fog set in and we fastened to a floe, which proved a bar
our further progress. Until August 26 we drifted with the same floe, more or less
uth, then steamed a short distance to northwest and fastened to another heavy floe,
hich, with the vessel, drifted south until October 9, when we found ourselves opposite
orce Bay, about ten miles from shore. Drifting west and south, we entered Smith
rait and soon passed by Cape Alexander.

October 14 was a thick, gloomy day, and on the afternoon of October 15 a heavy
uth and southeast gale set in, which proved disastrous to the greatest part of the
ew. At about 5 p. m. it was reported to Captain Buddington that the ice at the
arboard was setting off; all of us at once went on deck, found matters as stated by
e man on watch, and saw two icebergs, which evidently had caused the separation
the ice; large floes passed by, the ship laboring under heavy pressure, so much so
to make her crack and tremble. Captain Buddington gave orders to heave out on the
all provisions, clothing, and valuable papers, constantly kept in readiness on deck.
that time the vessel was raised to at least six feet from her water-mark.

Part of the crew, Captain Tyson in charge, went out on the ice to collect the
res and carry them to a stronger part of the floe. Working on board, hard and
ady, I finally left the vessel on the stern-line, intending to secure a bundle of books,
ich had fallen close to the floe's edge, and then return to the ship; but while
rying this bundle to a safe place, the ice broke up, the stern-line parted, the bow
ser slipped off the ice-anchor, and the vessel drifted off. Command to pull the
ts over to the remainder of the floe was given, and when accomplished every-
ly picked up whatever he could lay hands on. I jumped back to one of the small
es, endeavoring to find the box containing my papers, but without success, and
ore I could return water intervened between me and the large floe. Seeing the
w close by, two others and myself entered the same, and with a kiak-paddle pro-
led the scow across the crack to the boats. Voices, coming from other small ice
es, were heard, and the scow sent to the relief of those parties; but having shipped
reat amount of water the scow sunk close by the men she was to relieve, her crew
rowly escaping to the ice. One of the boats finally succeeded in collecting all hands
n on the ice upon the large floe. The gale still continued, snow drifted at a furious
e, and darkness inclosed us; the floe continued breaking up at the edge, and a con-
ial removal of our stores was found necessary. We worked hard and steady until
m., when, exhausted, we lay down on the ice, amidst the drifting snow and ex-
ed to the fearful tempest. The papers, which had left my possession, consisted of
following:

Private letters and documents.

Record of meteorological observations, reduced and corrected.

Book of comparisons, for the correction and verification of meteorological instru-
its and observations.

Table of relative humidity and dew-point for indications of the wet bulb, between
nd —50°.

History of the expedition, in journal form.

Meteorological journal, containing a detailed record of occasional observations
short discussions of marked meteorological phenomena.

Astronomical and geodetical observations, including surveys of all land discovered
corrected.

Observations on magnetic declination at numerous localities.

Observations on horizontal intensity of magnetism at Thank God Harbor by the-
ite magnetometer.

Botanical collection of plants between latitude 81° 26′ and 82° 07′ N.

11. Topographical map of Thank God Harbor and Polaris Bay, secured in a tin cylinder.

The morning following our disaster we found our floe wedged in between an iceberg and Northumberland Island and water apparently leading to the island We made two attempts to reach the island, but in both cases ice intervened. The last attempt was made after we had seen the Polaris rounding Cape Robeson, directing her course to Northumberland Island, and finally disappearing behind the same, without coming to our relief. At this second and last attempt we even had to abandon one of the boats at the opposite edge of the floe, and return to the other boat and provisions.

While on her way from Cape Robeson to Northumberland Island the Polaris once stopped, perhaps engaged in picking up provisions and the papers of Mr. Bryan and those belonging to me. After our second attempt to reach shore a heavy northeast gale set in, and next morning we found ourselves in the middle of the strait and on a small piece of ice which had broken off the large floe. With the large floe we lost the second boat, some provisions therein, a large canvas hut erected previous to our separation from the vessel, and six bags of bread stored in the hut. When the gale abated an inventory of the stores was taken and found as follows: several bags of clothing; several musk-ox skins; thirteen cases of pemican; fourteen hams; some canned meat; a small bag of chocolate; an A tent; instruments and a chronometer.

During the first two weeks of our stay on the ice, while drifting between Northumberland and Wolstenholm Islands, we built snow-huts and lived on seal-meat. Seeing that we might possibly exist during the entire winter even without fire and sufficient food, I ever afterwards nourished the hope of safely arriving at some port of Greenland during the following spring or summer.

The company laboring under such trying circumstances consisted of the following: Captain Tyson, assistant navigator, &c.; Fred. Meyer, meteorologist, &c.; John Heron, steward; William Jackson, cook; E. W. C. Kruger, Fred. Jamka, William Ludeman, Fred. Anting, Gustavus Linguist, Peter Johnson, seamen; Joe Eberby, Hannah, his wife, Punny, his child, Hans Christian and his wife, Augustine, Tobias, Sucei, and Francis Polaris, his children, Esquimaux; in all nineteen human beings.

On October 23, while close to Wolstenholm Island, our large floe was sighted, and at once all hands, accompanied by the dogs, went over to the same on the young ice. In the course of a few days we succeeded in bringing across to our encampment the second boat and provisions therein—six bags of bread, canvas and wood forming the large hut.

On the 28th of October the sun departed to his winter rest, leaving us to the mercy of the dark, dreary winter night. During the month of October the natives succeeded in shooting three seals. On November 1st an attempt was made to reach shore at Dalrymple Island, but we only succeeded to arrive, with boats, provisions, and one kiak, at the large floe, while on October 2 we drifted out off Wolstenholm Sound, and on October 10 we had passed the Carey Islands.

We settled down on the large floe, built snow-huts, and lived on bread and pemican: in all twelve ounces per day, which was warmed with a quart of water on a wood-fire—for firing material we cut up one boat—was issued to us in two meals; the natives whenever the weather would permit, went out hunting. During the month of November they killed five seals. Heavy winds prevailed, and we often were entirely blockaded with banks of drifted snow. On the 30th of November we sighted land, extending south from Lancaster Sound.

The month of December was mild, and we drifted so rapidly south that on December 21 we had light sufficient to read print during four hours of midday, and on December 7 I approximately determined latitude and longitude by α. Cassiopeia to 74° 04′ north 67° 53′ west; several bears and bear-tracks were seen, two white foxes and one seal killed; but in general we lived on the usual allowance of twelve ounces of bread and pemican, warmed up. In order to enable us to issue our provisions by weight, I previously had constructed a scale, by connecting a fine, three-cornered scale (rule) with a lever balance, taken from a broken aneroid, and attaching to the ends of the scale two cords two pasteboard boxes of equal weight; the weights I formed of chamois-skin and shot, taking as unit the weight of the meat contained in a one-pound can, and successively dividing it into half-pounds, four ounces, two ounces, and ounces.

On December 30 we sighted the west coast at a considerable distance. Approximate latitudes and longitudes were determined on January 6 by Polaris and α. Cassiopeia to 72° 09′ north, 60° 41′ west. On January 20, by the same stars, to 70° 02′ north, 61° 01′ west. On January 27, by the same stars and the sun, to 69° 32′ north, 60° 48′ west. On the 19th of January the sun was seen above the horizon during the course of two hours, and very likely had been out the day previous, but obscure to our sight by an iceberg bearing south.

On the 5th of January we had used up one boat, and from that time we warmed our meals on an Esquimaux lamp. January was stormy and cold; during this month we drifted very rapidly, and shot five seals. On February 5 I approximately determined by the sun, our latitude to be 68° 50′, and on February 19 Cape Walsingham

Digitized by Google

ıd neighboring land was in sight; preparations for an attempt to reach land were ade, but this plan finally was abandoned, and a reduction of our daily ration to seven nces found necessary, so that our provisions might hold out until the first of April. ebruary was mild but very stormy; during this month we drifted rapidly; six seals d a great number of dovekies were shot; unicorn, bears, and bear-tracks seen. March is stormy and changeable in temperature; during this month a great number of seals, me dovekies, and one bear were shot, and a number of unicorns seen. We lived in a ate of continual anxiety, the ice around us broke up, our floe parted into small pieces til we were confined to a space of about twenty yards in diameter; many nights we red not sleep, fearing the ice would break under our feet and we would find our grave the Arctic Sea.

Finally, on the 31st of March, our encampment became wasted out to such an extent at, on the 1st of April, we took the water, in the boat, endeavoring to penetrate the ck, where we expected to find protection against sea and weather. On the 12th of rch we were in latitude 64° 32′ north; on the 13th in 64° 19′ north; on the 17th in ' 47′ north; on the 22d in 62° 56′ north, and on the 31st in 59° 41′ north; we sighted land during this month. From April 1 to April 4, inclusive, we at times had leads water to south and southwest, which permitted us to proceed by oar and sail several es each day; but April 5 to 20 we staid on one and the same piece of ice, surrounded pack, and laboring under heavy-sea swell, which caused us much anxiety. Fre- ntly we dared not sleep, for fear the ice would break under our feet, or the sea wash off the ice. Several times the ice broke close to the boat and tent, and once ler the tent, while all of us were inside of it eating breakfast. At another time, ile half of us watched and the other half slept, the ice broke between the boat and t, and the general outcry was to stay with the boat; but on looking around I found self alone with the boat, all others having staid with the tent and provisions. I the kiak adrift; but it drifted in a direction opposite to where my comrades were. deavored to push the boat, which was heavily loaded, off the piece of ice; but before I ceeded the two natives, propelling a small piece of ice by a paddle, approached me. I ew out a line, and pulled them up to me. We, all three, succeeded in getting the t off, but I had the misfortune to go with it and fall in the water. Only a short ance from where we had started the boat got beset by pack-ice; after three hours' l work we succeeded in pulling up the boat on a piece of ice half of her size. There staid all night, and I, being wet through, was never before so near freezing to death; my breath for some time, but finally restored circulation of blood by a rapid motion ands and feet. At daylight we saw our comrades and tent about half a mile off. Cap- Tyson and some of the crew came over to us on the pack-ice, and working all together lragged the boat back to the tent; the kiak was found a short distance from the and also saved.

the night from the 19th to the 20th of April we were washed out of the tent, which lost, and we had to cling tightly to the boat during the entire night, or it would been washed off the ice, which actually took place, in carrying boat and men hang- o it from one side of the piece to the other, while ice-blocks three feet square pelted nst the boat and our legs. At last we launched the boat and arrived safely on a l but smaller piece of ice, which did not labor much under the heavy sea. On this the pack-ice again closed around us, and on April 22 our provisions consisted of ten biscuits. Starvation was before the door. Then Providence directed a bear to ncampment, and, while all others hid themselves, Joe and Hans from behind a mock shot the bear. We then crossed over the pack-ice to the place where the breathed his last, fastened a line to him and pulled him to our encampment. From time until finally relieved by the Tigress we had an abundance of meat, which we rally ate raw.

om April 25 to April 30 we had more or less opportunities to proceed by boat, but l on the ice, the sea washing over it, we were compelled to sleep in turns of half umber.

April 28, while proceeding in the water, we saw a steamer crossing our course at distance. The flag was immediately hoisted, but at dark the vessel was out of . Next day we again saw a steamer, launched the boat and proceeded by oar we arrived at a barrier of heavy pack, when we pulled up on a cake of ice, set ls for the steamer and fired shots. Four shots fired from the steamer were heard , and taken as answer to our signal-shots; but herein we were mistaken. Toward ng the vessel was lost out of sight. The morning of April 30 was thick and foggy. ain Tyson, myself, the steward, cook, and natives slept in turn from 12 m. to 5 a. hen we were roused by the watch to take their place; but before we had shaken l drowsiness somebody cried out: "Here is a steamer close by." We all cleared oat just in time to see the fog throwing his dark veil over the vessel so patiently l for. Then Hans had the admirable idea of taking to the kiak and apprising the l of our presence. The flag was hoisted, shots fired, and all hands hailed the ves- the highest pitch of their voices. I am unable to describe the sensation of relief I saw the steamer come to our encampment. All of us were taken on board the ss and treated hospitably.

Digitized by Google

April was mild but more or less stormy. During this month I have recorded a number of approximate determinations of latitude: On April 4, 56° 47′ north; April 55° 51′ north; April 12, 55° 35′ north; April 13, 55° 23′ north; April 14, 55° 13′ north; April 15, 54° 58′ north; April 17, 54° 27′ north; April 21, 53° 57′ north; April 28, 53° 30′ north; April 28, 53° 04′ north. The Tigress, a sealing-steamer, pursued her course during the next ten days. She then took us to Bay Roberts, and from there to Saint John's. At Saint John's we remained two weeks, when the Frolic, United States man-of-war, arrived, and returned with us to Washington.

II.—Scientific operations of the expedition.

1.—Astronomical and geodetical observations.

The Bureau of Navigation had provided the expedition with six chronometers, three sidereal ones, and three solar mean time. A daily comparison, made at six hours Greenwich mean time, showed that their relative differences generally kept increasing, according to their primary rate. All comparisons with their first and second differences were recorded in a book which, under charge of Mr. Bryan, would be found among his papers. The chronometers were known by letters as "A, B, C, D, E, and Z," and Z was selected as standard; they were in a gimbal box, which again set in a cushioned box, and were three together inclosed in two wooden, cushioned boxes, which, fastened to the cabin floor, set around the mast, but detached therefrom. Observing some of them on journeys while in charge, I gained some valuable experience. When, in June, 1872, we were on a journey to the north, the boat was crushed in the ice, I succeeded in saving chronometer "D." When gotten from the boat, the outside box was completely crushed and still, when compared with a hack-watch, the chronometer had kept its rate remarkably well. "D," then, was carried overland to the vessel, and forgotten to be looked a comparison at its arrival showed a loss of nearly thirty minutes. Taken out again the canvas-boat, our long stay on the bay-ice of Newman's Bay gave me an opportunity to ascertain the rate of "D" by observations on the prime vertical. In this manner found that although "D" had a larger daily loss on the ice than on board, this daily loss would remain the same while on the ice. When finally compelled to return shore during a southwest gale, "D" was left on a piece of ice, and during the storm exposed to the action of the waves, so that, when gotten the next day, the chronometer was found reversed; but compared with a hack-watch, the chronometer showed to have preserved its ice-rate.

A.—Astronomical observations at winter-quarters.

Preliminary observations, with sextant and artificial horizon, for latitude and were made on shore of Thank God Harbor the day following our arrival by Captain Hall, Mr. Bryan, and myself; carefully computed, and using the primary rate of chronometers, the position was found to be 81° 38′ north, 61° 44′ west—seconds I do not recall.

During the winter, observations for latitude were made upon stars, both north and south of the zenith, with sextant and artificial horizon, whenever the weather permitted to do so. After the sun's rise in spring a great number of equal altitudes near the prime vertical and of meridian altitudes, both upper and lower culminations, were taken with sextant and artificial horizon, as also with the theodolite. A great number of the moon's altitudes were taken whenever this satellite was visible. The transit instrument was set up at the observatory (see pl. I. T.,) on a stout piece of plank, which rested on two trestles, their legs being sunk into the ground and frozen tight, and passing through the floor without touching it. All constants were not known, but could be found, with the exception of the division value of the level, which finally was determined in the following manner:

I. The height of a great number of threads of the screw, acting vertically upon the rotation axis, was measured, and thereby the height of one thread found.

II. The length of the level measured.

III. The inclination of the level, corresponding to the height of one thread, found by

$$l \sin x = h.$$

l = length of level.

h = height of one thread of the screw.

x = angular value of level inclination corresponding to h.

IV. Division value of level determined by finding the number of turns of the screw corresponding to one division of the level.

The instrument, once set up in close approximation to the meridian, remained stationary, but the azimuth correction was observed for at the beginning and close of each set of observations by transits of stars of twelve hours' difference in right ascension, one cumpolar and one equatorial. A great number of level-readings (reversals) were taken before and after each set of observations; but frequently the difficulty arose that

Digitized by Google

bubble could not be made sufficiently small. Transits were timed by sidereal chronometer "A," which constantly remained at the observatory, fastened in a box to the transit-stand; a meridian mark was not established. Moon transits were observed at all occasions; also several occultations are on record. A great number of lunar distances, especially such measured from the sun, were taken. The index error of a sextant generally had to be determined before and after each set of observations, as great irregularities, caused by change of temperature, were observed. The repeating circle was used at times, but very seldom.

B.—*Astronomical observations on sea and in ports of Greenland.*

Between New London and Saint John's a great number of sun's altitudes were measured by Captain Hall for latitude and longitude. At Saint John's one of the chronometer-watches was compared with a chronometer which had been rated shortly before, and this comparison recorded. Between Saint John's and Fiskenaes a great number of determinations of latitude and longitude by sun's altitudes were made by Captain Hall and myself, as also between Fiskenaes and Holsteinborg. At Holsteinborg two sets of observations for longitude, by sextant and artificial horizon, were obtained by Captain Hall and myself. All four sets when computed resulted in one and the same longitude within one second of arc. Captain Hall also obtained an observation for the latitude of Holsteinborg. Observations for latitudes and longitudes between Holsteinborg and Godhavn are recorded, and at Godhavn Captain Hall obtained several sets for both latitude and longitude. At Upernavik observations with sextant and artificial horizon were made by Mr. Bryan and myself. Altitudes on the meridian and about four hours from the meridian were selected. At Tessiusak Captain Hall, Mr. Bryan, and myself made determinations for latitude and longitude. Between Tessiusak and Thank God Harbor a great number of sun's altitudes, for the determination of latitudes and longitudes, were made. The last observation on sea was made for latitude by all persons capable, and for longitude by Captain Hall and myself; the result I think was 81° 24′ north, 64° 35′ west. Between Thank God Harbor and Northumberland Island a great number of observations on latitude and longitude, with sextant and artificial horizon, were made by Mr. Bryan and myself. Those made by me while drifting in Smith Sound are now in my possession, and, together with bearings of headlands, appended in Paper I; they generally are taken on the prime vertical, so that latitude and longitude deduced therefrom refer to one and the same position. In Paper I, I give resulting latitudes and longitudes, having applied the primary correction and rate of chronometer "Z" from memory.

C.—*Astronomical and geodetical observations, forming a series of systematic surveys.*

Thank God Harbor and Polaris Bay were surveyed by me in September, 1871, with the theodolite and plane-table. The plane-table was constructed under my supervision by Mr. Shuman, first engineer, in the following manner:

I. A drawing-board was mounted upon the tripod, sent with the dip-circle, by a center clamp-screw.

II. The round level of a chemical scale was detached therefrom, to be used in leveling the plane-table.

III. A round compass was sunk into a four-cornered elongated box, so that a line connecting N and S of the graduated arc would be parallel with the side of the box.

IV. The telescope sent for observations of pendulum transits was mounted upon a metal rule, so that when placed upon a horizontal plane the telescope-axis would be parallel and in a vertical plane with one edge of the rule.

Before the commencement of operations with the plane-table, I obtained the co-ordinates of three marked field-points by using chain and theodolite. All points are referred to the position "Observatory." I then entered upon the plane-table the three points mentioned above, and point "Observatory," where I took my first station. The table leveled and brought into parallelism with the field, a line marked "N" and parallel with the connection of N and S of the graduated arc of the compass-box and the N and S of the needle, was drawn, as also sight-lines to all points desirable to be taken on by the survey. The second station was taken three or four miles from the first, the table leveled, the box-compass applied to line marked "N," and the table brought into approximate parallelism with the field. Then cutting in backward, a small triangle would be obtained in place of the correct station-point. This station-point had to be either to the right or to the left of all sight-lines forming the triangle, and its distances from these sight-lines had to be in proportion with its distances from the field-points employed in forming the triangle, therefore a simple geometrical construction would furnish the correct station-point, when the table could be brought accurately into parallelism with the field; sight-lines to all points, taken in at the first station, would be drawn, &c.

For the verification of this plane-table survey, I determined a point "D" twelve

Digitized by Google

miles from observatory, with the theodolite and chain, and found a sensible agreement of its determination by theodolite with that by the plane-table.

As soon as the survey of Thank God Harbor and Polaris Bay was completed, I drew an elaborate topographical map of the same before the disappearance of the sun.

During the spring and summer of 1872, I made surveys of the east side of the channel from latitude 80° 27′ north to 82° 21′ north; of the west side of the channel from latitude 80° 15′ north to about 84° north; of the interior, between Newman's Bay and Polaris Bay, of Newman's Bay, and to some extent of the interior northeast of Newman's Bay. All these surveys were executed by taking up a great number of stations at Polaris Bay, Newman's Bay, and intermediate points, determining their latitude, longitude, and magnetic declination by theodolite, and taking magnetic bearings to all points desirable to be taken in by the survey. In this manner between 300 and 400 points were determined and known by numbers. Sketches of coast-lines and hill-ranges, to serve as a basis for the detail of a topographical map, were also made. When, while going north, our boat was crushed in the ice, I lost the theodolite, and ever afterwards I took the bearings with a large azimuth circle, taken off a large prismatic compass. This azimuth circle, supplied with a vernier and sight-vanes, I mounted upon a tripod, and leveled it with a round level. Determinations of latitudes and longitudes had to be made with sextant and artificial horizon; for determination of magnetic declination, a prismatic compass was employed. In July, 1872, I visited the north side of Repulse Harbor, made observations for latitude and longitude with pocket-sextant, using sea-horizon, and measuring the elevation by aneroid. I then saw the west side of the channel bending to the south of west in about latitude 84° north, and the east side of the channel to the south of east in about latitude 82° 21′.

Repulse Harbor's latitude is about 82° 09′ north; its longitude between 58° and 59° west. The Southern Fjiord was to some extent surveyed by Mr. Bryan in the spring of 1872; its head has not been seen; and, when passing its entrance in the fall of 1872, on our route home, I was impressed that the Southern Fjiord was a channel in reality, and perhaps connected with "Emperor Joseph's Fjiord" of the German expedition. "Lady Franklin's Bay" also appears to be the junction of two channels separated by an island. While on our home route Cape Constitution was recognized by Mr. Morton and Hans. Observations made in its vicinity proved its latitude to be about 80° 27′ north. While drifting through Smith's Sound, a great number of astronomical observations, in connection with bearings to headlands, were made by Mr. Bryan and myself; those made by me are now in my possession, and appended in Paper I. On our voyage north, as well as our voyage south, it generally was felt that the west side of the channel, as laid down in Dr. Hayes's map, needed considerable alteration; not in the detail of the map, but in latitudes, longitudes, and general direction of coast line. Kennedy Channel at parts is very narrow, especially in the vicinity of Cape Constitution, where its width hardly exceeds from fifteen to twenty miles. Cape Ritter Bay, on Dr. Hayes's map, the northern extremity of Kennedy Channel, really is the southern extremity; the two sides of Kennedy Channel consist of land, which is mapped neither by Dr. Kane nor Dr. Hayes; the direction of "Humboldt Glacier" very likely, is not north and south, but northeast and southwest, &c. In plan II I append a diagram of Smith's Sound, Kennedy Channel, Polaris Bay, Robeson Channel, and of the west coast to about latitude 84°. All records of astronomical and geodetical observations would be found partly among Mr. Bryan's and partly among my own papers. During the winter of 1871 to 1872, I constructed the ship's track between New London, latitude 82° 16′, and Thank God Harbor. The Polaris before she started had not been swung and her compass deviation therefore was unknown.

As from St. John's to latitude 82° 16′ our mean course was north, I approximately determined the deviation by merely computing the position in which the log, without the use of any deviation, would locate Fiskenaes at; the angular value of distance "computed position and real position of Fiskenaes," with radius equal to distance "St. John's and Fiskenaes" furnished the deviation which in proceeding north varied proportionally to the tangent of the magnetic inclination. The limits of sea-currents I could very well determine by the change of surface sea-temperature, and by the combination of all meteorological instruments motion. It is very interesting that the state of atmosphere over the Labrador current, between Newfoundland and St. John's, as indicated by the combination of all meteorological instruments, is so marked and peculiar that I afterwards was enabled, without using the sea-thermometer, exactly know when we entered the Labrador current between St. John's and Greenland, when we arrived at its center line, and when at its northern limit. In a similar manner I had all other currents indicated, compass deviation and limits of currents determined; the velocity of currents was found by dead-reckoning; astronomical observations made at latitude 81° 24′ north; longitude 64° 35′ west, and Thank God Harbor served as verification.

2.—MAGNETIC OBSERVATIONS.

A.—Differential observations, for the determination of diurnal variation of magnetic declination, were made at the observatory of Thank God Harbor. The theodolite was

Digitized by Google

meter was used therefore in the snow-hut "M," (pl. I,) upon a stout wooden
d, which was solidly frozen into the ground; a thermometer was suspended from
stand. When first the instrument was set up, and the line of detorsion brought in
cidence with the magnetic meridian, it remained undisturbed during the course of
or five months, when hourly readings were taken by Dr. Bessels, Mr. Bryan, and
lf, besides readings, at five minutes interval, on term days, prescribed by "Ridell,
During these observations the collimator magnet was suspended in a stirrup,
tructed by Mr. Shuman, the original stirrup having been lost when the gale of
mber 22 blew down the snow-hut; only a single fiber was used during these ex-
nents. The disturbances were large and frequent; and therefore the record of
ential observations consists of scale readings, azimuth-circle readings, and ther-
etric readings, and is kept in one book, which will be found among Mr. Bryan's
rs.
—Observations on absolute magnetic declination were made by Captain Hall at
avn and Thank God Harbor by prismatic compass, sextant, and artificial horizon.
ain Hall also recorded a great number of the sun's bearings with the course of the
l while between Tessinsak and Thank God Harbor. Mr. Bryan made determina-
of absolute declination at Thank God Harbor by theodolite magnetometer, and
theodolite, and, while drifting in Smith's Sound, by prismatic compass, sextant,
rtificial horizon. His determination at winter-quarters with the theodolite mag-
neter was made by reference to two very marked field-points, to which he had
ured a great number of solar bearings. I made determinations of absolute decli-
n by either small theodolite or prismatic compass, sextant, and artificial horizon,
ank God Harbor, Polaris, and Newman's Bay, as also at a great number of inter-
ate points. While drifting in Smith's Sound I determined the declination at all
when recording magnetic bearing of marked headlands. Captain Hall's observa-
on magnetic declination are among his papers, and undoubtedly on board the Po-
Mr. Bryan's determinations were in his box thrown on the ice, and are probably
on board the Polaris. Determinations made by me were in my box, and may also
nd on board the vessel. The observations made while drifting in Smith's Sound
ow in my possession, and will be found appended in Paper I. Declination at
k God Harbor was about 96° west. Mr. Charles A. Schott, before the expedition
d, prepared a map exhibiting the isogonic lines in the vicinity of the north pole,
cannot but state that Mr. Schott's isogonic lines almost entirely coincided with
based upon our observations.
-Observations on relative magnetic intensity were made repeatedly at Thank God
or by Mr. Bryan, and will be found among his papers.
ervations on absolute, magnetic, horizontal intensity were made by me in the
r of 1872, at Thank God Harbor, and consist of—
eral sets observations on the zero divisions of collimator magnet and week mag-

eral sets of vibrations with and without ring-weight.
he exact weight of the ring, found with a very sensitive chemical scale, and its
sions.
eral sets of deflections at two distances.
etermination of the scale value of the collimator magnet.
sets of vibrations are accompanied by observations on the co-efficient of torsion.
observations extend over the period of about eight days or longer, and their
will be found among my papers. During these observations the magnet, then
original stirrup, which had been recovered in spring, was suspended on three

Observations on magnetic inclination were made by Mr. Bryan with the dip-circle
siusak, Thank God Harbor, and Southern Fjiord. At Thank God Harbor the in-
on was determined very frequently, and all observations were recorded by Mr.
among whose papers they will be found.

3.—OBSERVATIONS ON THE FORCE OF GRAVITY.

ng our stay at winter-quarters the pendulum was swung on the same
dges as previously at Cambridge and Port Foulke. Transits of the lower
dge over the vertical hair of a telescope, set at a distance of about twelve feet
cidence with the zero of the graduated arc, were observed by Mr. Bryan and
relieving each other, while Dr. Bessels timed the signals given by the observers
transits. The azimuth of the plane of vibration was nearly north and south;
e of the pendulum apparatus, placed at P (pl. I,) rested upon heavy planks,
were frozen into the ground; it was carefully detached from the floor and wall
observatory, and supported by three steel braces, one in the back and one on
le. The plane supporting the knife-edge was kept carefully leveled; the semi-
unted from the middle either way, frequently recorded, as also the readings of
ronometers, placed respectively at heights of the lower and upper knife-edges.
of transits were marked by sidereal chronometer "A," whose rate was observed

Digitized by Google

for, before and after these pendulum experiments, by Mr. Bryan. All four faces were swung in strict compliance with the manuscript instructions prepared by Mr. Charles A. Schott. The readings of barometer are furnished by the meteorological record.

The record of our pendulum observations when completed was placed in the hands of Dr. Bessels, and undoubtedly is now on board of the Polaris; the pendulum itself will also be found at the vessel.

4.—OBSERVATIONS ON OCEAN PHYSICS.

A.—*Observation on depth.*

Soundings were made in latitude 81° 24′ north, longitude 64° 35′ west, and at a great number of positions in Smith's Sound. The record of two soundings in Smith's Sound is now in my possession, and, together with bearings of the positions to known headlands, appended in Paper I. The record of all other soundings is among Dr. Bessels's papers.

B.—*Examination of sea-bottom, procured by either dredges or soundings.*

Dredges were made at St. John's, and surface-dredges on the greatest part of our route between Tessinsak and Thank God Harbor.

Sea-bottom was taken up with each sounding. All dredges and portions of sea bottom were examined by Dr. Bessels; the results of these examinations are recorded among his papers.

C.—*Observations on sea-temperature.*

Surface sea-temperature was observed by Dr. Bessels and myself between New London, latitude 82° 16′ north, and Thank God Harbor, as also, while returning, between Thank God Harbor and Northumberland Island, at most times hourly, but sometimes every three hours. They are very interesting and instructive in defining currents. Sea-temperatures at the bottom and intermediate points were recorded whenever an opportunity was offered to observe them.

The Miller-Casella's deep-sea thermometer proved useless when exposed to the colder waters and climate, the transparent liquid contracting disproportionately. All observations on sea-temperature are recorded, together with the systematic meteorological observations, and are among my papers; Dr. Bessels has an extract of sea-temperature observations.

D.—Observations on the density of sea-water simultaneous with observations on sea-temperature by hydrometrical measurements were made by Dr. Bessels and myself. Dr. Bessels also had a number of sealed bottles filled with sea-water of different localities and intended for chemical analysis.

E.—*Observations on currents.*

As I have stated above, the observations on currents were not directly made, but indirectly, by observations of sea-temperature and meteorological observations; the velocity of currents could be deduced from the log. Along the coast of Greenland, at the season of July and August, observations on sea-temperature give very interesting indications. The sea-thermometer gives proof of a continual variation of surface sea-temperature, nearly equidistant from the temperature of maximum density of salt-water. Per example: at one locality we find the temperature +43°; not far from it we find it +35°; this shows that surface and under currents are interminglings, caused by their almost equal specific gravity.

Crossing Smith's Sound, and getting within the vicinity of the west coast, we met a cold current, directed to the southwest, which, higher up in Kennedy Channel, Polaris Bay, and Robeson Channel, was noticed to take up the entire width of the straits. The direction of this current was beautifully illustrated by a line of icebergs seen in Smith's Sound, bearing northeast and southwest. The velocity of the current I computed from the log, making use of our observations of latitude 81° 24′ north, 64° 35′ west, and found it to be nine miles per day. This was afterwards verified by the computed distance between the position the vessel got beset in and the position she broke out at, giving thirty-six miles for a four day's drift. The position she got beset in depended upon the observations of latitude 81° 24′ north, longitude 64° 35′ west, and the log; the position she broke out at depended upon Thank God Harbor and the log.

F.—Tidal observations were made at Thank God Harbor by some of the seamen with a tide-guage, constructed on Dr. Hayes's plan. These observations extend over the entire winter, from September, 1871, to June, 1872, are made at times every ten minutes or half-hourly, or hourly, and their record is among Dr. Bessels's papers.

The rise and fall of the tide is small; the age of the tide nearly twenty-four hours

Digitized by Google

5.—METEOROLOGICAL OBSERVATIONS.

A.—*Observations on atmospheric pressure.*

uring the voyage from New London to Thank God Harbor, observations were made ry three hours with a marine barometer and an aneroid; both instruments were t compared with Green's standard barometer, No. 739 (?); the indications of the ometer were very marked over every branch of a cold current, as also their gradual ease and decrease in approaching or distancing the parallel of maximum pressure. instruments were kept in a shelter, fastened to the port side of the wheel-house, their indications corrected for temperature, elevation, and instrumental error. At ter-quarters observations on atmospheric pressure were made hourly at the observ- y with Green's standard barometer, No. 739 (?), and were corrected for tempera-, elevation, and instrumental error. The elevation above the mean level of the sea termined in the fall, and again in the spring, by the theodolite, and I constructed, aplace's formula, a table giving the correction for said elevation at temperatures n +50° to —50°. All the barometers in the possession of the expedition I kept care- compared; it frequently was found necessary to clean the mercury of No. 739 (?); ll such occasions comparisons were made before and after its cleaning.

ne motion of the barometer-column was very marked, with northeast and south- t winds, being very fluctuating and generally high, but falling with a northeast l, and very low, but rising with a southwest wind. These indications are very sig- ant, and varying according to season. In the fall, when an immense quantity of sture is precipitated from the higher regions in form of fogs, frost, smokes, snow, and ation of fresh-water ice on the sea, the barometer is very low; the same in spring, n active evaporation of snow, ice, and water is going on. Between Thank God bor and Northumberland Island hourly observations were made and corrected. A ber of measurements of elevations by aneroid I made at and between Polaris and man's Bay. Before I left Washington I compared Green's No. 739 (?) with the bu- standard and Naval Observatory barometer.

—Observations on temperature were made every three hours on our voyage north, y hour on our voyage south, and at winter-quarters.

ter my separation from the vessel I made some notations of temperature, which ppended in Paper II. On our voyage north the influence of cold sea-currents over spheric temperature was especially marked. On several other journeys, it was al- observed that ice will form on the salt-water whose temperature is below 32°, even n the atmospheric temperature is +40° and higher. This ice-formation is congealed -water, which partly melts off the surface of drifting ice and partly condenses on from atmospheric moisture. At winter-quarters I operated very carefully, in r to get true observations of atmospheric temperature. As soon as practicable our arrival at Thank God Harbor, I made at the observatory a long series of com- ons, at different temperatures, of all thermometers on board. Green's thermome- after application of their correction, previously determined at Washington, agreed st to the tenth of a degree; especially two mercurial thermometers, of which I ted one as standard. Casella's thermometers showed more or less irregularities, h, I think, was caused by their being encased in wooden frames. A great number ermometers were suspended in the shelter "5," pl. (1,) on a revolving drum of e-work. The temperature was noted always by the standard, but at the freezing ne mercury all thermometers in the shelter were registered, corrected according to ious comparison, and the most probable temperature of the melting of mercury ced. The melting-point of mercury, by repeated operations, as described above, found —39°.8. One of Green's spirit-thermometers most correctly showed the erature of melting of mercury by applying the correction found from previous parison. This thermometer I selected for the notation of atmospheric temperature v melting of mercury. Very annoying, in regard to the observation of thermome- was the almost continual snow-drift, which, besides burying the thermometers en- , almost blinded the observer. I am astounded how quick a tolerable observer, under such difficult circumstances, will acquire the routine of just bringing the of a lantern to bear upon a thermometer, and reading it correctly to one-tenth degree during the period of one second. At Thank God Harbor the highest tem- ure observed was between +40° and +50°; the lowest temperature, —58°, oc- d in January, but March was the coldest month.

the fall, with a northeast wind, the temperature would rise; with a southwest, it d fall. In spring a northeast wind would be preceded by high temperature, de- ing after the northeast wind had set in; a southwest wind in spring was preceded w temperature, rising after the wind's arrival. In winter a northeast wind pre- l by low temperature would produce a slow rise; a southwest wind preceded by emperature would produce a rapid rise of temperature.

—Observations on winds were made every three hours on our voyage north, every on our voyage south, and at winter-quarters. The direction of winds on board of

Digitized by Google

the vessel was determined by comparing it with the compass and application of magnetic declination. The velocity of winds was found by the anemometer erected on the quarter-deck, port side, or the current meter whenever the former was obstructed. Between St. John's and New London one cup of the anemometer was carried overboard, and as I wished to reserve one anemometer for winter-quarters observations, I continued the observation of the anemometer, running on three cups, and deduced true velocities from its indications by the formula—

$$V_x = V \frac{4\,W}{3\,W_x}$$

which I constructed in the following manner:

Let

P represent the force of wind, in pounds, on a square foot.
L resistance of atmosphere upon one cup during one revolution.
R friction at spindle while in motion on four cups.
R′ friction at the spindle while in motion on three cups.
a area of the half-sphere, forming the concave slide of a cup.
b area of the base of the cup.

During one revolution of a cup, the direction of the wind forms with the base of the cup all consecutive values of angles, (from 0° to 360°,) and therefore the force exerted upon a square foot of the cup at any time is expressed by—

$$P \sin z$$

but during half a revolution the wind exerts its force upon *a*, and during the other half upon *b*; expressing the differential of *z* by *d z*, and the entire force exerted by the wind upon one cup during one revolution is equal to—

$$\frac{P f \sin z\, d\,z\,(0—180)}{d\,z} \cdot a + \frac{P f \sin z\, d\,z\,(180—360)}{d\,z} \cdot b = \frac{2\,P\,(a—b)}{d\,z}$$

and upon four cups, equal to—

$$\frac{8\,P\,(a—b)}{d\,z}$$

this force is diminished by the resistance of atmosphere 4 L and friction R, and the total force in action becomes—

$$\frac{8\,P\,(a—b)}{d\,z} — (4\,L + R)$$

In a similar manner, the total force in action upon three cups is equal to—

$$\frac{6\,P\,(a—b)}{d\,z} — (3\,L + R')$$

But, according to the law of inertia, two forces are proportional to the masses they set in motion; and also to the velocities they communicate to said masses. Expressing the mass or weight of four cups, stems and center-piece by W_x; the weight of three cups, stems and center-piece by W; the velocity of four cups, under pressure P, by V_x; the velocity of three cups, under pressure P, by *v*, we will have the equation—

$$\frac{\frac{8\,P\,(a—b)}{d\,z} — (4\,L + R)}{\frac{6\,P\,(a—b)}{d\,z} — (3\,L + R')} = \frac{W_x\, v_x}{W\, v}$$

transforming—

$$\frac{8\,P\,(a—b) — (4\,L + R)\,d\,z}{6\,P\,(a—b) — (3\,L + R')\,d\,z} = \frac{W_x\, v_x}{W\, v} \quad \text{or}$$

$$\frac{4}{3} = \frac{W_x\, v_x}{W v} \qquad \frac{v_x}{v} = \frac{4\,W}{3\,W_x}$$

considering that the velocities of the cups at any time are proportional to the indications of the anemometer, and if we express the indications of the anemometer while running, respectively, on four and three cups, and under influence of pressure P, by V_x and V, we have—

$$\frac{V_x}{V} = \frac{v_x}{v} = \frac{4\,W}{3\,W_x} \qquad V_x = V \frac{4\,W}{3\,W_x}$$

At winter-quarters the direction of the wind was determined by reference to marked field-points, whose true bearing was known accurately. The anemometer was erected

Digitized by Google

about fifty yards from the observatory, free of obstruction; the velocity of wind was
arly determined, and the number of miles for the preceding hour noted also.
n cases of doubtful observations or very light winds, the current meter was besides
ught into action. Anemometers were always kept in the best order; Mr. Sherman,
engineer, repaired the spindles several times by replacing the brass tops by steel
s. Frequent comparisons of anemometers and current meter were made. The prin-
l direction of high winds and gales at Thank God Harbor was northeast in fall
spring, and northeast and southwest in winter; the entire winter was almost a
inuation of heavy gales.
ortheast gales showed different features, and, as it appears, these characteristics
e very marked, if I distinguish two classes of northeast gale:
Such as were the primary impulse of a violent commotion of atmosphere, inducing
uthwest gale at an adjacent place.
Such as were induced by a southwest gale in action at an adjacent place.
is evident that in the arctic regions, where sea channels and streaks of land follow
gular order, polar currents will always select their paths, either on land or on sea,
cordance with the greatest tension of atmosphere, dependent upon the season;
will induce a southwest wind, which, on the contrary, selects its path wherever the
the most rarefied; a mutual displacement takes place, and two gales blow in op-
e directions at adjacent places. This frequently was actually observed at Thank
Harbor and vicinity.
re are the characteristics of the two classes of northeast gales:
ien a primary impulse, a northeast wind was always preceded by high atmos-
c pressure, low temperature, and almost entire absence of moisture; veerings at
ommencement and close of the gale were in accordance with the law of gyration.
ig the gale the barometer would fall, the thermometer would rise, and relative
dity increase.
ien a secondary action, a northeast wind was preceded by low atmospheric pres-
high temperature, and low relative humidity; veerings before and after the gale
place contrary to the law of gyration. During the gale the barometer would rise
y, temperature would almost remain stationary, and relative humidity would
ise rapidly.
*t*hwest gales also had two different characteristics:
'receded by low barometer, high temperature, and relative humidity; veerings
and after the gale, in accordance with the law of gyration; rise of barometer,
thermometer, and stationary relative humidity during the gale.
'receded by low atmospheric pressure, high temperature, and low relative humid-
'eering before and after the gale, contrary to the law of gyration; rise of barom-
all of thermometer, and rapid rise of relative humidity during the gale.
ocities above forty miles per hour were very frequent; light and pleasant winds
observed from all points of true bearing.
r my separation from the vessel, I frequently noticed the direction of the wind,
notations I append, in Paper II.
Observations on clouds were made at times of systematic observations; forma-
similar to those known in our climates, were noted; strata were prevalent, and
rus cloud was seen in the region of cumuli.

E.—*Observations on precipitations, &c.*

ipitations in form of heavy snow or rain were rare, but very frequent in the
fog, frost, smoke, haziness, and light snow. It frequently was observed during
nmer that when moisture was precipitated over an area consisting partly of
id partly of ice, it would take the form of rain on land, but the form of snow on

Observations on ozone were made daily; no ozone was obtained on our voyage
more or less ozone was noted at winter-quarters, and some on our voyage
At winter-quarters, and during the winter, the greatest amount of ozone was
d with northeast winds, but especially with heavy snow-drifts. During the
ozone was very abundant, and decreasing in the fall.

G.—*Observations on solar and terrestrial radiation.*

ngs of the vacuum black-bulb thermometer and the free black-bulb thermom-
re taken hourly in 1872, while the sun was above the horizon.
thermometers, after a rigorous comparison with the standard, I placed in a
tal position on crutches, about half a foot above the ground, where I spread a
canvas, thickly covered with cotton wadding.
vations on terrestrial radiation were made hourly, at Thank God Harbor, with
bulb spirit-thermometer, which, after comparison with the standard, I placed
izontal position on crutches, its bulb immersed in cotton wadding.
ed bulb spirit-thermometer was placed in a horizontal position, its bulb in the
a silvered concave mirror, and frequently observed.

Digitized by Google

The vacuum solar radiation thermometer at times showed above + 100°.

The terrestrial radiation thermometer at times showed close to — 70°. Condensation of moisture on instruments placed out-doors in form of beautiful crystals, (arabesques,) took place quite frequently.

H.—*Observations on crystallization of snow.*

All snow-crystals consisted of hexagonal prisms, either single or in numbers, arranged to forms similar to those observed by Scoresby and Belcher. When single they frequently were deformed, and quite frequently different forms were precipitated simultaneously.

I.—Observations on moisture with the psychrometer were made every three hours on our voyage north; hourly, on our voyage south. At winter-quarters I took special care to operate in such a manner as to enable me to keep an hourly continuous series of observations on relative humidity and dew-point. In order to judge such observations as to their accuracy, and to operate accordingly, it was necessary to once construct a table exhibiting relative humidities and dew-points, at temperatures between 0° and — 50°. This I executed in the following manner:

1. I computed the elastic force of vapor of saturated air for every tenth of a degree, by the exponential formula:

$$\log e = a - bA^x - cB^x$$

$$\log A = 1.9940493 \quad \log b = 0.1397743$$

$$\log B = 1.9983438 \quad \log c = 0.6924351$$

$$a = 6.2640348.$$

which formula represents best Regnault's entire experiments on the elastic force of vapor of water.

2. The elastic force of vapor, corresponding to readings of the psychrometer, I computed by—

$$x = f - \frac{14.256\,(t - t')}{1240.2 - x\,t'}$$

3. Corresponding relative humidity found by—

$$r = \frac{f\,100}{F}$$

4. Corresponding dew-points found directly from results of (I.)

I then prepared a spirit-psychrometer by cutting off the lower part of the frame of the two best Casella's spirit-thermometers, to bring their bulbs under perfect exposure to the air. A thin muslin was tied to one of the bulbs, and both thermometers were rigorously compared with the standard by which their relative correction, difference of indications, were accurately ascertained. During the entire winter hourly observations of the psychrometer were made, and the relative humidity and dew-point deduced therefrom in the manner shown by the following example:

Reading of standard	— 20.3
Correction to naval standard	— 0.4
True temperature of atmosphere	— 20.7

A. Reading of dry-bulb.	B. Reading of wet-bulb.
— 21.2	— 21.3
	Difference of A and B when dry — 0.3
	— 21.6
	— 21.2
	Difference of dry and wet-bulb + 0.4
	— 20.7
	True temperature of wet-bulb — 21.1

Entering the table, previously constructed, with temperature of wet-bulb = — 21° and difference of dry and wet bulbs = 0.4, the corresponding relative humidity and dew-point would be found immediately. I frequently experimented with Regnault's dew-point instrument for the verification of psychrometer observations, having

Digitized by Google

ously ascertained the relative difference of the two thermometers of the instrument
rigorous comparison with the standard.
The following example will show how, from the indications of the instrument, I de-
iced the true dew-point:

Reading of standard.	— 23.4	Reading of dry thermometer.	— 25.2
Correc'n to naval stan'd	— 0.4	Temp. of atmosphere	— 23.8
True temp. of air.	— 23.8	Correction of dry thermometer	+ 1.4
Reading of wet thermometer			— 27.8
Difference of dry and wet bulbs, when both dry			— 0.7
			+ 1.4
True dew-point			— 27.1

simultaneous observations of psychrometer and dew-point instrument, when re-
ed in the described manner, resulted in values of the dew-point never differing by
re than 0°.5.
The general features of atmospheric moisture at Thank God Harbor are very marked.
fall almost perfect saturation took place by the gradual precipitation of moisture
umulated in higher regions; in January almost entire dryness was observed, and
pring a rapid increase of relative humidity is on record. The fluctuation of moist-
, in relation to certain winds and atmospheric pressure, I have already described.
.—Experiments on atmospheric electricity were made during the winter, but with-
result. Both instruments used, a gold-leaf electroscope and an electrometer, con-
icted especially for the expedition, were very sensitive and were frequently hoisted
pole to the height of from twenty to thirty feet, but without result. I afterward
structed a collection apparatus similar to the one first described by Romershausen,
permanently connected the same in the proper manner with the electroscope.
arrangement would enable the observer on watch to at once notice the presence
tmospheric electricity. I frequently tested this apparatus by applying an electri-
glass cylinder, when the gold-leaf would immediately diverge. The collection ap-
atus was mounted on a pole, twenty-five feet high, and properly insulated; the
troscope had a ground connection by which it could be switched off.
—Auroral phenomena were of frequent occurrence in latitudes between 50° and 65°
h, and very brilliant; rare in latitudes between 65° and 75° north, and frequent at
er-quarters, but faint, and only exhibiting white light. The general characteris-
of aurora at Thank God Harbor were one or more continuous arches of perfectly
e light and faint streamers, which were observed at almost all points of true bear-
These streamers at most times were observed directly opposite the true bearing
e sun, then below the horizon. Luminous appearance of the heavens in a similar
ion to the sun was also very frequent, and, after a prolonged discussion of the sci-
ic members of the expedition, classified as aurora. Only one complete aurora,
ing three different coronas and of a rosy tint, is on the record of Thank God Har-
This auroral display took place in the evening of some day of February, 1872,
ig the morning of which fluctuations of the needle, through about 12°, were ob-
d; smaller disturbances were observed during the display. This aurora un-
tedly is identical with the great aurora of February 4, 1872, as it is the only red
een by us. Not being in possession of an instrument, observations on the auroral
rum could not be made. At times haziness and slow precipitation of very minute
-crystals accompanied auroral displays. Experiments on the fluorescence of the
a have not been made.

M.—*Observations on height of twilight arcs.*

ilight arcs were observed even when the sun had its greatest south declination;
uration of twilight was always recorded. I also made several measurements with
extant of the height of the twilight arc, but not as frequently as I would have
d to do, had the light and state of atmosphere been more favorable in rendering
rc sufficiently distinct for measurement. This measurement, when compared
the sun's declination, always showed an 18° distance of the twilight arc from the

N.—*Optical phenomena.*

ages, halos, parhelia, and paraselene were of frequent occurrence; observations on
olarization of light of the sky could not be made for want of an instrument.

O.—*Observations on meteors.*

reat number of shooting-stars were observed, especially in November; several
; meteors are on record.

Digitized by Google

P.—*Miscellaneous observations.*

The line of perpetual snow must be placed above the height of 1,700 feet, as in July, 1872, I found such an elevation entirely bare of snow.

Observations on evaporation were made, but had to be abandoned on account of condensation of atmospheric moisture and snow-drift.

Minute drops of mercury froze as readily as large masses.

After our arrival at Thank God Harbor I selected the times of observation, so that three of them were taken, respectively, at 7.35 a. m., 4.35 p. m., and 11.35 p. m., Washington mean time.

On our voyage north, all observations were made by Dr. Bessels and myself, relieving each other in eight-hour watches. From our arrival at Thank God Harbor until the middle of January, I observed the instruments during sixteen hours and Dr. Bessels during eight hours.

By the middle of January I considered Mr. Mauch, whom I had instructed in making observations, sufficiently advanced, and ever after Dr. Bessels, Mr. Mauch, and myself took eight-hour watches.

The complete meteorological record, corrected and reduced by me, the book of comparisons, table of relative humidity, meteorological journal, &c., were among my papers.

An incomplete copy of the meteorological record, uncorrected, is on board of the Polaris.

6.—NATURAL HISTORY.

All notes and collections referring to this branch are in the hands of Dr. Bessels, with the exception of a botanical collection among my papers.

7.—GEOLOGY.

Notes and collections in reference to geology are also under charge of Dr. Bessels.

8.—NO OBSERVATIONS ON GLACIERS ARE ON RECORD.

Drift-wood, which has been collected on the southern shores of Polaris Bay and Newman's Bay, and signs of Esquimaux, as the runner of a sled, and Esquimaux weapons, are among Dr. Bessels' collection.

The largest part of the instruments under my charge were lost at our separation from the vessel; all books under my charge will be found on board of the Polaris, with the exception of the Müller Pouillet.

PAPER 28.

WASHINGTON, D. C., *September* 30, 1873.

SIR: In accordance with instructions received from Colonel Mallery, I have endeavored in the short time at my disposal to prepare a brief preliminary account of the severe cyclone that visited the shores of Nova Scotia and Newfoundland on the 24th and 25th of August last, where it did immense damage; and have also given some attention to the preliminary storm of August 13 and 14, which was severely felt on the shores of New Jersey.

In preparing the maps which accompany this report, an attempt has been made to gather in from all possible sources of information such meteorological observations as, although somewhat crude, may enable us to obtain a better understanding of the extent of these storms. To this end application has been made through Captain Howgate for the logs of a number of vessels that have passed in or near the regions visited by the storms in question. A list of the sources of information will be found in the Appendix No. 1, and it is proper here to state that the office is especially indebted to the kindness of the Hon. Secretary of State; the Hon. Secretary of the Navy; Prof. Joseph Henry, of the Smithsonian Institution; Mr. Lorin Blodget, of Philadelphia; the representatives at Washington of the New York Herald, Times, and Tribune, and the Boston Advertiser and Journal; Dr. Smallwood, of Montreal; Professor Kingston, of Toronto; the captains of the steamship Sonora, brig Dorothea, steamer E. M. Arndt; Mr. T. C. Hill, of Sidney, Cape Breton; W. Allison, of Chatham, Cape Breton; and Mr. L. Clift, of Harbor-Grace, N. F., for courtesies shown in the supplying of such material as was available for the purpose in hand. In Appendix No. 2 will be found a list of those vessels whose logs were used in connection with the observations made upon shore.

Besides the meteorological features of the hurricane, the great destruction of life and property has rendered it proper that I should prepare a brief statement of such details as have been collected up to this date. In this work I have been especially assisted by Sergeant Pearson, who has prepared a detailed map and the accompanying table, (Appendix No. 3,) in which is shown the geographical distribution of the damage done to life and property. The sums-total given in this final table are evidently far within the probable truth, and I have thought it not improper to make the following slight additions in order to arrive at a more correct idea of the ravages of this terrible storm: One thousand and thirty-two vessels, of which four hundred and thirty-five were small fishing-schooners, are known to have been destroyed during the 24th and 25th of August in the neighborhood of the Gulf of Saint Lawrence and the Atlantic shores of Nova Scotia, Cape Breton, and Newfoundland. On the other hand, over ninety vessels were destroyed by this hurricane in the course of its passage over the ocean before reaching Nova Scotia, making a grand total of at least one thousand one hundred and twenty-three vessels destroyed within a few days by its power. Two hundred and twenty-three lives are definitely reported as lost, and the most moderate estimate of the numerous

Digitized by Google

cases in which whole crews are stated to have been lost swells this number to nearly five hundred, while if to this is added the loss of life on land, and the loss in the earlier history of the cyclone, the grand total amounts to at least six hundred lives. The summary given shows that little less than nine hundred buildings were damaged or destroyed during the 24th and 25th of the month. Any endeavor to estimate the value of the property destroyed is attended with great difficulties, but may be within bounds if to the seven hundred thousand dollars damage done to wharves and crops is added one thousand dollars for each building, two thousand dollars for each of the larger vessels, and one thousand dollars for each of the smaller vessels, which would give a total of three and a half millions of dollars, a sum that it will be seen may easily be far below the truth. It is not unimportant to here remark that the ravages of this storm have very seriously crippled the interests of the American and Canadian fisheries, and that the loss falls with special severity upon Gloucester and other cities of New England.

The following maps accompanying this report give a general view of the progress of this storm:

Map No. VII shows the meteorological conditions at 4.35 p. m., Washington time, August 23.

Map No. VIII shows the meteorological conditions at 4.35 p. m., August 24.

Map No. IX shows the conditions at 11 p. m., August 24.

Map No. X shows the conditions at 7.35 a. m., August 25.

Map No. XI shows the conditions at 4.35 p. m., August 25.

On the latter chart the previous track of the storm, as far as it has been traced, is also given; and in Appendix No. 12 is a table giving the geographical positions of the storm-center, showing it to have been one of a not very large class of cyclonic storms that, beginning in the West Indies, work westward and northward, up between the Bermudas and the Atlantic coast, and then turn northeastward toward Newfoundland. It is scarcely to be doubted that such a storm as this must have continued its course for several days longer toward Europe; and it is an interesting fact that the Bulletin International of the Paris Observatory shows that a severe storm moved over the northern portion of Great Britain on the 31st of August, reaching Norway on the 3[illegible] September; and although no logs of vessels have yet been received from the eastern half of the Atlantic Ocean sufficiently precise to establish the details of the connection between this European storm and that of the preceding days in Nova Scotia, yet the interval of three and a half days is so short as to leave no reasonable doubt but that they were identical.

It has frequently been stated that while no doubt could exist as to the identity in general of the great American and European storms, yet that no single instance of the kind had as yet been well established. It is to be hoped that the present contribution to this subject may be considered as removing all doubt on this matter, although pains will be spared to secure further testimony.

The principal features of the weather in the Middle and Eastern States during the period embracing the present study may be briefly summarized as follows:

On the morning of the 12th an area of slight barometric depression existed west of the Alleghanies. The temperature throughout that region was of about the normal value; the wind light and variable. The influence of this depression was, however, already perceptible on the Middle Atlantic coast, where easterly winds with clouds and light rain were reported, while over New England and Nova Scotia the barometer stood somewhat about the average value, with northerly winds and clear weather. Vessels off the coast reported northeasterly winds, and those over a hundred miles distant designated these as gales. By the morning of the 13th the barometer had fallen decidedly on the Middle Atlantic coast, and northeasterly winds increasing about to [illegible] with rain prevailing throughout these States, while in New England the pressure had slightly risen, it being apparently highest at that time over Maine and New Brunswick. The indraft of air from the ocean continued during the 13th and until the 14th producing, as has been quite frequently noticed on other occasions, a continued increase of the disturbance that had been initiated the previous day along the Atlantic coast. very heavy rains fell during the night, and a secondary barometric depression appears on that morning to have been central over the peninsula lying between the Chesapeake and Delaware Bays. It is, perhaps, impossible to say whether this depression originated in Virginia or off the Atlantic coast, and whether it had moved northeastward or northward.

This delicate point could have been settled, probably, had we been able to obtain any accurate meteorological reports from the peninsula in question; as it is, the depression passing through Delaware on the nights of the 13th and 14th was apparently accompanied by two, if not three or four, smaller storm-centers, which, being of the nature of tornadoes, seemed to have done considerable damage, both by wind and rain, in Eastern Pennsylvania and in Maryland. The most severe winds were, as always the case, reported from the New Jersey coast; and, destructive as these northeasterly gales were to property on the land, it is satisfactory to be able to refer to the

Digitized by Google

ter of Captain Felber, of the steamship E. M. Arndt, who testifies that, being on s way to New York with a disabled propelling-screw, and relying entirely upon the nds, he was fortunate enough to obtain a copy of the New York Herald on the 10th August, of the preceding day, containing the prediction of continued northeasterly nds along the New England coast, and relying upon this, made a speedy and safe ssage to the harbor of New York, which he entered at 6 p. m., August 13. The orm which on the morning of August 14 was probably central near Long Branch, w Jersey, appears to have increased somewhat in size and severity during the day, oducing brisk and high northeasterly winds in Southern New England, which in- ase was, however, quite in accordance with our previous knowledge of the diurnal owth and subsidence of these phenomena. Owing to the presence over a large body cold, dry air to the northward, the meteor could advance but very little in that ection; it appears rather to have moved directly eastward, or possibly east-north- stward, and, on the morning of the 15th, to have been about one hundred miles th of Cape Cod, while northeasterly winds, diminishing in force and backing to th, prevailed, with clouds and light rain, in New England.

During the 15th easterly winds with rain prevailed at Halifax, and the disturbance ms to have almost completely died away. It is important to notice that, while this mparatively insignificant storm was thus passing northeastward over New Jersey nd Nova Scotia, the barometer had steadily risen at the Bermudas, with light nds and pleasant weather on the 16th, but with somewhat stronger southwesterly nds and rain on the 13th, 14th, and 15th. The highest pressure of the month was ined at the Bermudas on the 18th of August, and rainless weather continued in se islands from the 16th to the 21st of the month; indeed, the drought of August September has been much complained of by the residents of those islands. Dur- the former interval the cyclone, which has been frequently termed the great va Scotia cyclone, was steadily developing some five hundred miles to the thward. The first report that has reached us concerning this hurricane is obably that of the 13th of August, when the bark Crest of the Wave reported eavy gale veering from northeast to southeast in latitude 14° and longitude ; as, however, our next definite information concerning the hurricane is dated the 18th of the month, it would be too much to assume more than that the ther experienced by the bark Crest of the Wave was intimately associated with early history of the Nova Scotia cyclone. The observation, however, deserves e recorded, inasmuch as several of these storms are already known to have origin- not far from the region in which the Crest of the Wave then was, and it is rom impossible but that we shall, by further diligent collocation of ships' reports, ble to carry back the history of the Nova Scotia cyclone from the 18th to the 13th ugust, and possibly still further, and to show that this belongs to the class of nes that originate near the coast of Senegambia, and distinguished from those originate further to the west. Be this as it may, the history of the Nova Scotia ne since the 18th of August seems to be sufficiently clear. It was at noon of that in about latitude 22° and longitude 60°, with light northeast winds and falling meter at the Bermudas; at noon of August 19th it was in latitude 22°, longitude at noon of August 20th, in latitude 27°, longitude 66°; at noon of August 21st, titude 30°, longitude 67°.5, with falling barometer and strong northeasterly winds ing to southeast at the Bermudas; at noon, August 22d, it was in latitude 33°.5, longitude 68°.5; at noon of August 23d, in latitude 37° and longitude 67°, with nwesterly gales at the Bermudas. At this time the barometric depression attend- he cyclone seems to have extended to a distance of at least five hundred miles nwest and northward of its center, with falling barometer and cloudy weather ted in New England and Canada, while the report from Mount Washington s continued northwesterly winds.

the multiplicity of conflicting accounts concerning the positions of vessels and the her experienced by them on the 23d, 24th, and 25th of the month, it is difficult to y that desire for the exact truth which should guide the study of nature; and in g, as my conclusion, that the center of the cyclone and its most terrific mani- ion of power did not pass directly over Nova Scotia, but kept perhaps two hun- miles off its coast, I am aware that discrepant observations may be adduced cting with this conclusion. It is my belief, however, that at midnight of the 25th, the center of the storm must have been in latitude 44° and in longitude 56°. s about this time that the lowest barometers were experienced at Halifax, Sidney, ottc Town, and also on board several vessels at that time near the coast of Nova . Between sunset and sunrise of this night occurred the greatest destruction of d property in this region, due to a terrific easterly wind, which within twenty- ours backed from southeast to northwest. On the 25th at noon the storm was ently central in latitude 44°.5 and longitude 54°.5. It was at this time that the barometer was reported on the Magdalen Islands, Gulf of St. Lawrence. It is to narked, however, that the lowest reading of the barometers in Nova Scotia and lf of St. Lawrence when reduced to the sea-level do not fall below 28.90, while

Digitized by Google

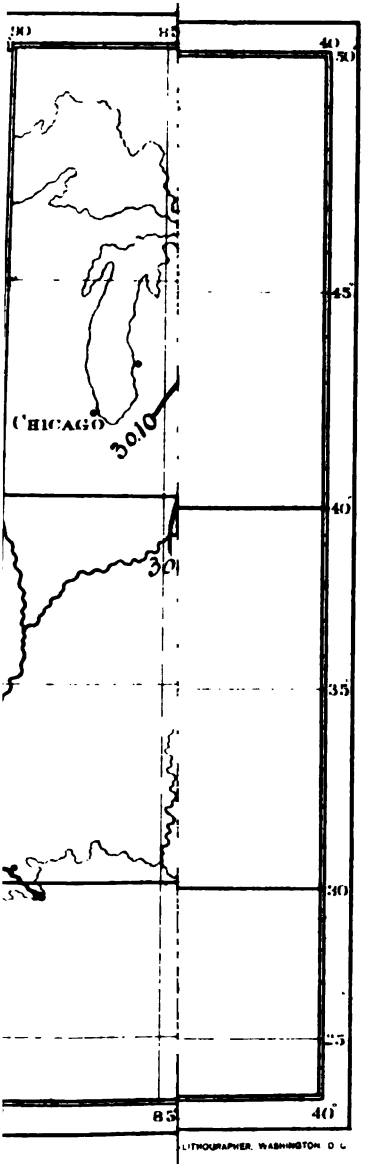
the occasional reports of barometric readings made by vessels at sea, incorrect though they may be, owing to our ignorance of the errors of the instruments, yet uniformly point to a pressure at least as low as 28.30 inches near the center of the cyclone. On the 25th at midnight it is impossible to locate the region of lowest barometer nearer than is indicated by the winds at Harbor-Grace, Newfoundland, and Cape Breton which point to the center as being in latitude 46° and longitude 52°. At noon of the 26th the center must have been about latitude 47°.5 and longitude 50°. At this same rate of progress the center would at noon of the 27th be in latitude 49°.5, longitude 54°.5. The accompanying table, Appendix No. XII, gives in addition to the preceding positions, which are comparatively well established, also the positions of the barometric depression that reached the shores of Great Britain a few days subsequently, as shown by the Bulletin International; this disturbance was apparently far less severe than that of Nova Scotia, which is in accordance with the well-recognized general rule that these storms gradually extend over a large circular area, and, after diminishing in force, completely break up on encountering large continental masses of dry air.

In connection with this brief sketch of the progress of the Nova Scotia cyclone, I would respectfully direct your attention to the fact that whenever we have telegraphic communication with the Bermudas it will become possible to greatly extend the scope of the storm-predictions, and by the co-operation of the fast-sailing European steamers to forewarn vessels leaving the ports of the United States of the existence of any cyclone that may be in progress some distance off the coast. It is indeed evident that as any portion of the territory covered by the signal-service stations is liable to storms approaching from the southeast, southwest, or northwest, it should be equally protected, if possible, on all sides. The advantages of an extended correspondence with navigators have been very strongly felt in the prosecution of this work, and a very considerable extension in this direction of the work of the signal-service would seem to be justifiable.

I have the honor to remain, very respectfully, yours,

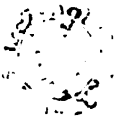
CLEVELAND ABBE.
Assistant, Office Chief Signal-Officer.

Brig. Gen. A. J. MYER,
Chief Signal-Officer, United States Army.



APPENDIXES TO THE REPORT ON THE NOVA SCOTIA CYCLONE OF AUGUST 24-25, 1873.

APPENDIX No. I.



The following sources of information have been examined:.

Signal-service stations, forms 4, MSS.
Signal-service stations, journals, MSS.
Canadian stations, forms 4, MSS., (excepting Saugeen, Port Dover, Port Stanley, Quebec, and Kingston, Canada, for week ending August 30, and Halifax and Chatham, N. B., for week ending August 23.)

APPENDIX No. II.

List of vessels from which information has been received concerning the Nova Scotia cyclone of August 24-25, 1873.

America, steamship.
Australia, steamship.
Atlantic, bark.
Arthur, brig.
Assam Valley, ship.
Albemarle, steamer.
Athena, bark.
Alexander, bark.
Belle Stewart, bark.
Brazos, bark.
Crest of the Wave, bark.
Dos Hermanos, schooner.
Dundee, brig.
E. M. Arndt, steamer.
Excelsior, brigantine.
Emma F. Lewis, schooner.
Esperanza, ——.
Ellen Southard, ship.
Ella Maria, brig.
Edinburgh, steamship.
Everhard Delins, bark.
E. M. Seeds, bark.
Guldfaxe, ship.
Hound, brig.
Helen Sands, bark.
H. M. Crosby, schooner.
Helicon, ship.
Hoogly, ship.
Hebe, ship.
Helvetia, ship.
Hammonia, steamship.
Importer, ship.
Italia, steamship.
J. Morton, brig or schooner.
Jas. Kenway, bark.
Kingston, brig.
Louise, bark.
La Plant, steamship.
Lookout, schooner.
Lapland, steamer.
Mary Louise, fishing-schooner.
Minnehaha, ship.
Mary S. Lunt, schooner.
Mercur, bark.
Napier, schooner.
Nora, ship.
Orinoco, bark.
Oceanic, steamship.
Oak Point, brig.
Pennsylvania, steamship.
Primera, bark.
Russia, steamer.
Reform, bark.
Ravenwood, brig.
Saint Olaf, steamship.
Saltwell, steamship.
Sappho, schooner.
Susan E. Voorhees, brig.
Scindia, steamship.
Spirito, bark.
The Brothers, schooner.
Thos. Dunham, ship.
T. Arthur, brig.
Tenax Proposite, bark.
Young Eagle, bark.
Zizine, bark.
Zuleima, bark.

APPENDIX No. III.

Details of loss or damage incurred in storm of August 24-25, 1873, at Cape Breton, Gaspe, Labrador, Magdalen Islands, New Brunswick, Newfoundland, Nova Scotia, and Prince Edward Island.

Vessels described as fishing-schooners entered under the head of "small" vessels; all her under the head of "larger" vessels.

Digitized by Google

Lives lost: numbers only given where definite information has been received: crews, where "all hands" are reported lost, have been estimated at 10 for each crew.

Amount of property in dollars only contains such items as have been reported.

Buildings damaged or destroyed: contains all buildings, of whatever description, where numbers have been given.

All loss or damage described as "immense," "great," "several," "many," "incalculable," "unlimited," "very large," &c., has not been allowed for in total.

Names of places.	Vessels damaged, stranded, or wrecked.		Lives lost on land or at sea.	Amount of property reported in dollars.	Buildings damaged or destroyed.	Remarks.

Schooner Reindeer struck on beach at Clay Banks and sprung a leak; repaired at Manitowoc.
Tug B. F. Bruce aground in Detroit River.
Ferry-steamer Hattie Brown broke her shaft.
Tug Rob Roy broke her wheel near Oswego.
Barge Herschel and schooner St. Peter collided at Chicago.
Schooner Lomie A. Burton jammed in Lake Erie; pulled off by a tug.
Steamer Ballantine broke her shaft on Lake Erie.

13th.—Propeller Merritt foundered on Lower Saint Lawrence; crew all saved.
Schooner Northern Belle sunk by collision with schooner Annie Vought in the straits. Vought slightly damaged and Northern Belle a total loss.
Schooner Nabob badly damaged by collision with bark Elizabeth Jones near Sheboygan.

14th.—Steamer Northwest broke her wheel at Cleveland.
Schooner Adriatic badly damaged by colliding with schooner Mary off Chicago, during a heavy squall, and had to be towed back.
Schooner City of Milwaukee struck by lightning at Cleveland.
A colored fireman of tug Wm. Pringle drowned in Saginaw River.
Propeller City of Toledo broke her shaft at Chicago.
Schooner Eveline Bates parted her chain and drifted against pier at Kelly's Island.

16th.—Schooner Comanche damaged on Saint Clair Flats.
Schooner Harvest Home lost main-boom during a squall off Grand Island, Lake Superior.

17th.—Patrick McNamara, a sailor on schooner Pilgrim, was drowned off Chicago.
Scow Eugene had her foremast and head-gear carried away by collision with a tug near Marine City.

18th.—Schooner Eureka ashore at Port Colborne; got off.
Tug B. W. Aldrich burned at Ludington.
Tug Mystic broke her shaft on Lake Saint Clair.
Schooner William Elgin sprung a leak and put back to Kingston for repairs.
Schooners Eagle Wing and Donaldson, ore-laden, ran aground on Saint Clair Flats; lightered off without much damage.
Steam-barge City of Port Huron and barge Dictator on the rocks at Nebish Rapids.
Canal-boat Jesse Van Riper sunk by collision at Black Rock.
Schooners Kate Lyons and Welland damaged by collision off Chicago.
Schooner S. J. Luff struck a reef near the straits and damaged her forefoot and keel.

19th.—Steam-barges Fred Kelly and Robert Holland ran aground in Saint Clair Flats.
Schooner E. R. Blake ran ashore in Green Bay; lightered off.
Schooner Gold Hunter struck on bar while leaving Vermillion Harbor; repaired at Cleveland.
Schooner Morning Star lost mainsail and after-rigging by being run into by the Prince of Wales off Nine-Mile Point, Lake Erie.
Tug A. F. Bartlett broke her cylinder-head at Detroit River.

20th.—Schooner Persian ashore at Evanston; got off without damage.
Propeller Equinox aground on Saint Clair Flats; pulled off by tug Merman.

21st.—Propeller Winslow aground at Bar Point, Lake Erie.
Steam-barge Chas. Reitz badly damaged by collision with tug Johnson at Chicago.
Schooner Conquest and tug Wood damaged by collision with tug Harrison at Chicago.
Schooner Enterprise run into by propeller Clematis at Chicago.
William Sinclair, sailor, drowned in Saint Clair River.

22d.—Schooner Barber had her stern badly damaged by being run into by barge coming at Chicago.
Schooner Ariadne ran on the Ducks on Lake Ontario, during a fog; pulled off without damage.

23d.—Tug H. P. Clinton and a vessel ashore at Malden; released without damage.
Schooner Josephine ashore at Pentwater; got off.
Scow Alpena water-logged on Lake Erie; towed to Cleveland.
Barge Sandusky damaged by collision with bark Maria Martin at Milwaukee.
Propeller Bruno ashore in Detroit River.
Propeller S. D. Caldwell damaged stem by collision in straits.
Steamer Jay Cooke broke rudder at Toledo.

24th.—Steamer Ballentine struck a rock at entrance to Detroit River, and sprung a leak; towed to Detroit for repairs.
Schooner E. P. Dorr, corn, ashore on Charity Shoals, Lake Erie.
Schooners Odin and Denmark badly damaged by collision off Ahnapee, Lake Michigan.
Schooner Antelope sprung a leak at Port Huron.

25th.—Schooner Two Brothers lost jib-boom and foremast-head, off Oswego, in gust of wind—towed back for repairs.

8th.—Tug Prindiville ran into ferry-scow at Tonawanda and cut her in two. Damage, $600.
9th.—Schooner Flying Mist ran foul of schooner Mary A. Wand and lost her anchor. The Wand badly damaged.
Schooners Keith and Regular damaged by collision at Chicago.
Schooner W. H. Willard lost jib-boom on Lake Michigan.
10th.—Steam-barge Vanderbilt ashore at Pike's Bay, Lake Huron.
11th.—Tug H. N. Martin and schooner Melvin damaged by collision with bridge at Cleveland.
Canal-boat Samuel Morgan sunk at Buffalo; 8,200 bushels corn damaged.
Bark Oneonta reached Chicago minus her foretopgallantmast.
Schooner Sardinia arrived at Chicago in a sinking condition.
12th.—Schooner A. C. Maxwell, ore-laden, ashore at Bar Point, Lake Erie. Jettisoned part of her cargo and got off.
John Cadath, sailor on Barge Fulton, seriously injured by a fall through a hatchway at Bay City.
Steam-barge Mary Groh sprung a leak at Cleveland.
Scow Sassacuss ran ashore at Ford Shoals. Pulled off by a tug.
13th.—Barge J. D. Morton, during rough weather on Lake Erie, broke loose from tow of steam-barge Sun, and went to pieces.
Barges Globe and Sunburg run ashore on Kelly's Island. Globe raised and towed to Buffalo, Sunburg to Detroit.
Schooner David Stewart arrived at Cleveland in a leaking condition.
Steamship W. T. Graves put into Milwaukee in a disabled condition. Boiler gave out.
Schooner S. S. Osborn lost her bowsprit and head-gear by collision on Lake Huron.
Scow Senator had her foretop-mast broken and lost canvass during a squall on Lake Erie.
Propeller Shickluna, salt, struck the rocks and sunk on Weaver's Point, Lake Ontario. Raised and towed to Kingston.
A barge reported ashore on Chick-a-no-la reef, Lake Erie.
14th.—Schooner Chapin arrived at Chicago, leaking badly.
Schooner Carolina Marsh lost eight or ten thousand feet of lumber of deck-load by a gust of wind while off Oswego.
Tug W. B. Castle and schooner Ætna shored on Middle Ground at Point Edwards. Got off with slight damage.
Scow-barge H. G. Williams ashore on Cedar Point, Sandusky Bay. Total loss.
Daniel Berry, lock-tender, drowned in the Welland Canal.
15th.—Schooner S. Armsden slightly damaged by collision at Cleveland.
Brig Pilgrim lost her top-sail yards during storm off Chicago.
Steam-barges New Era and General Paine, with barges in tow, put back to Chicago on account of heavy weather.
Charles Nelson, sailor, of bark Carrier, fell overboard and was drowned.
Bark Menominee and schooner Sinai lost their top-sails on Lake Michigan during a storm.
Tug Edward Gallagher exploded her boiler on Torch Lake, Lake Superior. J. H Olds, of Hancock, instantly killed.
16th.—A sailor, of schooner Minerva, jammed between tugs Lowie Dole and Annie L. Smith at Chicago, and injured so that he died in a few hours.
Barge Sunshine became water-logged and lost deck-load of lumber off Bark Shanty, Lake Huron.
Schooners Addie and Dora disabled by a storm on Lake Michigan. Put into Benton Harbor.
Schooners Gifford and Ætna collided on Lake Huron. One man lost and one badly injured.
17th.—Steam-barges Buffalo and Bradbury had a rough passage across Lake Huron and barges Sunshine and Saint Clair in tow were water-logged.
18th.—Judson Mesler, sailor on schooner Wm. Jewett, drowned off Sodus.
19th.—Schooner J. Rigler lost part of canvass off Forty-Mile Point.
Schooner Kearsarge became water-logged on Lake Michigan and was towed to Milwaukee by propeller Lawrence.
Alexander Campbell, captain of bark Manzanilla, drowned at Port Dalhousie.
20th.—Henry Alston, sailor of Bark J. G. Masten, fell into river at Buffalo and was drowned.
Schooner Laura ran aground at month of River Thames.
Schooner Wm. Jones lost jib-boom, &c., by colliding with bridge at Chicago.
21st.—Steamer Atlantic lost mast by collision at the head of Saint Clair River.
Brig Starlight and schooner Cortez damaged by collision near Mammy Judy light, Detroit River. Schooner Cortez damaged to extent of $400.

d.—Schooners Japan and Planet damaged by collision off Sheboygan. Planet put into Sheboygan for repairs.
Tug Black Ball cut off the stern of schooner Maria Martin, and damaged her to amount of $1,000 by collision in Detroit River.
Schooner Milwaukee Belle ashore on Chambers Island, Green Bay. Threw deck-load overboard and got off.
John Hunter, mate of schooner West Wind, drowned off Toronto.
Tug Witch of the West broke her shaft at Bay City.
Steam-barge Vanderbilt on bar mouth of the Thames River.
Schooner Laveland damaged chain-flutes, &c., in a jam on Saint Clair Flats.
d.—Barge Oliver Cromwell and brig Orkney Lass sprung a leak while lading at Marquette, Lake Superior, and sunk beside the docks.
Alonzo Pearson killed by falling from mast of schooner F. Morell.
Steamer Eva English damaged on Saginaw River.
Schooner Express damaged on Lake Erie.
Schooner M. L. Collins ashore in Detroit River.
h.—Schooners Westchester and Flying Mist damaged by collision at Chicago.
Schooner Mary Collins lost jib-boom and bowsprit by collision with propeller Arizona at Erie.
h.—A small schooner sunk by striking dock at Chestnut-street bridge, Milwaukee. Raised and repaired.
Barge Saint Clair water-logged on Lake Huron.
Scow Planet sprung a leak at Milwaukee.
Schooner C. Harrison became water-logged at Evanston, and was towed to Chicago.
Propeller City of Fremont burst a flue on Lake Michigan. Detained seven or eight hours.
Schooner A. W. Lacky, ore-laden, broke her rudder on Saint Clair Flats.
Steam-barge Vienna and barge Verona ashore at Presque Isle, Lake Huron. Vienna got off without damage and Verona filled with water.
Steamer Young America ran ashore on Fighting Island.
Schooner S. P. Ely aground in Nebish Rapids.
.—Propeller Oneida struck on Belle Isle; aground fourteen hours and got off.
Schooner Marion Egan ashore at Cove Island, Georgian Bay. A total loss.
Schooner Gerritt Smith sprung a leak in the straits. Towed to Detroit by the tug Leviathan.
Schooner Maggie M. Rae water-logged on Lake Erie. Towed to Detroit River and there capsized.
.—Schooner Montana, ore-laden, grounded on Belle Isle, Detroit River.
.—Schooner Senator passed Detroit in a dismasted conditon.
Alexander Ross, mate of bark Tanner, was drowned at Buffalo.
Bark Acorn put into L'Anse, Lake Superior, in a leaking condition.
Schooner Comanche shifted cargo and arrived at Oswego with nearly 1,000 bushels wheat wet.
Eli Smith, sailor of barge Severn, drowned at Buffalo.
Steam-barge Mary Robertson arrived at Chicago in a leaking condition.
Propeller Waleska broke her wheel at Chicago.
.—Propeller Cleveland ashore at Middle Island, Lake Huron. Pulled off with slight damage.
Byron Robinson, of yacht Mazeppa, drowned at Coburg.
Barge Comet became water-logged on Lake Michigan. Towed to Chicago.
Schooner Cambridge struck and sunk while leaving L'Anse, Lake Superior.

PAPER 30.

WAR DEPARTMENT, OFFICE OF THE CHIEF SIGNAL-OFFICER,
Washington, D. C., July 26, 1873.

SIR: I have the honor to report as follows: Having, in accordance with Special Orders No. 67, arrived at the scene of the tornado in Iowa, I there, to the best of my ability, endeavored to carry out the special instructions which I had received. The result is contained in the report herewith submitted.

Very respectfully, your obedient servant,

JAS. MACKINTOSH,
Observer-Sergeant Signal Service, U. S. A.

Gen. ALBERT J. MYER, *Chief Signal-Officer of the Army.*

WAR DEPARTMENT, OFFICE OF THE CHIEF SIGNAL-OFFICER,
DIVISION OF TELEGRAMS AND REPORTS FOR THE BENEFIT OF COMMERCE.
Washington, D. C., May 26, 1873.

SERGEANT: Upon arriving at Washington, Iowa, in compliance with Special Orders No. 67, O. C. S. O., of this date, you will at once proceed to the scene of the recent tornado near that place, and locating the point where it first struck the earth, will follow its path as far as its progress can be distinctly traced, giving particular attention to the following points suggested by the Chief Signal-Officer:

1. Trace accurately the course of the tornado, and determine whether its movement was direct, or whether it swerved at any time from a direct course, and, if so, the cause of such deflection.

2. Ascertain the velocity of wind in the whirl of the tornado; estimating this, as more accurate data cannot be had, from its effect upon inanimate objects, as for example, weight of objects moved, with area of surface of such objects exposed to the action of the wind.

3. Ascertain if objects were carried directly upward in the interior of the whirl without a whirling motion and thrown out at top, or whether they ascended in circles, whirling upward with the whirl of the tornado.

4. State if there are any evidences that the center of the tornado was a vacuum, as for examples: were trees wholly stripped of bark; did houses explode outward.

5. Ascertain if the tornado appeared to be attached at its upper extremity to a mass of clouds, or to a single and small cloud.

6. Were there any electrical discharges accompanying the tornado?

7. Was the tornado seen, before its complete formation, as a tongue of cloud hanging down from a mass of clouds?

8. Did it any time cross a body of water; and, if so, did it assume at that point the character of a water-spout?

9. Did the tongue of cloud, reaching toward the earth, distinctly whirl itself, or was it stationary, with a whirling column of air rushing up its interior?

10. Collect reliable data as to the greatest height to which objects were elevated and their weight.

11. Ascertain the condition of air outside the tornado, and whether the wind blew toward it from all directions.

12. Were there any premonitory signs of an approaching storm before the tornado struck the earth?

13. Where did the tornado originate, and where terminate?

14. Determine particularly whether the cloud from which the tongue of cloud depended had a rotary motion, or whether the tongue of cloud itself had one.

15. Duration of tornado, and progressive velocity.

16. Actual width of belt affected by the tornado.

17. Note the general direction of prostration of trees, being careful to allow for change of direction caused by striking the earth.

18. You will prepare a series of questions to which answers will be obtained from the most intelligent citizens living in and along the track of the tornado, so that same questions may be answered by different persons.

Digitized by Google

In addition to these points, you will investigate such others as will tend to give a connected and full record of the origin, progress, and disappearance of the meteor.

Having completed your investigation of the Iowa tornado, you will proceed to the location of the one reported in Illinois as raging on the same date, and follow out the same course of inquiry as for the Iowa storm.

Take ample time to do the work thoroughly, and report your location from time to time by telegraph.

Very respectfully, &c.,

H. W. HOWGATE,
Second Lieut. and Bvt. Capt., Acting Signal Officer and Assistant.

Sergt. JAS. MACKINTOSH,
Observer Signal-Service, U. S. A., Washington, D. C.

THE IOWA AND ILLINOIS TORNADO OF MAY 22, 1873.

STATEMENT OF THE FACTS.

This tornado could not by its destructive efforts upon trees, buildings, &c., be traced farther back than section 35, Warren Township, Keokuk County, Iowa. At the point where the destruction commenced, the South Skunk River bends southward and then again to the east, thus half inclosing a low level area of about one mile in length by half a mile in breadth. This bottom-land is surrounded by bluffs about 70 feet in height on nearly all sides, the river flowing close to the bluff on the southwest. It was at the northeast edge of this natural amphitheatre that the tornado first attained force sufficient to demolish fences. These fences were thrown down by a southwest wind for a space forty rods wide. The buildings of W. W. Morrow, situated half way up the bluff, were partly destroyed. But although its first destructive efforts were here manifested, it by no means follows that this was the starting point of the tornado. On the other side of South Skunk River, directly opposite, there was a strong wind, accompanied with some hail and rain, while to the north and west a tremendous rain fell, preceded and accompanied by large hail. The storm evidently arrived at Morrow's farm a well-nigh full-formed tornado. To trace it backward over a country where its phenomena were only those of a violent thunder-storm, I found to be difficult and deemed unnecessary.

The attempt to prove a connection between this tornado and the thunder-storm near Des Moines of May 22, 4 a. m., has not been successful. For although the Des Moines storm exhibited tornado-like power, since the distance between Des Moines and Morrow's farm is only seventy miles, and since the Des Moines storm occurred ten hours previously, its rate of motion, if it is identical with the Keokuk County tornado, cannot have exceeded seven miles per hour in a straight line. But, as will afterwards be shown, the tornado traveled more than twenty-nine miles per hour. This objection is by no means insuperable when viewed in the light cast upon the subject by the general modes of movement of storm-centers across the continent. These tornadoes, however, exist as something independent and automatic within the limits of areas of low barometer, and since their motion is governed by laws peculiar to themselves, it must meanwhile be accepted as valid. Besides, a hail-storm traversed Keokuk and Washington counties May 22, at 6 or 7 a. m. There is much more probability of a connection between this hail-storm and the Des Moines storm of 4 a. m. than between the latter and the tornado which occurred eight hours subsequently.

In the Neosho County Journal, of May 24, is an account of a highly destructive tornado which desolated a portion of Lincoln county six miles long by one-half mile wide. This tornado was apparently every whit as violent as that in Iowa. The time at which it occurred is given as about 3 p. m. It cannot, therefore, be identical with the subject of this paper.

The conclusion follows that, wherever this tornado may have originated, it first attained to desolating violence on Morrow's farm. Its previous history was only that of a thunder-storm, accompanied, perhaps, by an unusual tumult and whirling of the clouds. In tracing its development and progress, therefore, I probably labor under no disadvantages which do not necessarily attach to the history of all such meteors except those arising from the circumstance that the tornado was not at any point of its progress witnessed by a skillful meteorologist.

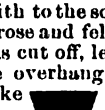
Mr. Morrow testified that neither he nor any of his people noticed any funnel-shaped appearance or tongue of cloud approaching the earth. There was a strong wind for a minute, but the destructive gust appeared to be instantaneous. A smart shower of hail followed the gust. A whirling of the clouds was observed several minutes before the wind. A little lightning was seen. The storm traveled east-northeast over Andrew

Digitized by Google

Surber's farm, blowing down fences, with a southwest wind. He saw the cloud whirling like a great wheel 35° in width before the storm, but did not notice any funnel appearance. A few hail fell with the wind, and a considerable shower of rain after it.

The same phenomena were repeated on J. E. Storer's farm. A steady roar was heard as it approached. No lightning seen.

About forty rods north of the line of destruction on these farms resides William P. Liske. He saw two clouds, one in the southwest and the other in the northwest, which appeared to rush together in the west. As the tornado came up, and about twenty minutes before it arrived, the wind changed to the north and blew so strong that the door had to be held to prevent it from being blown in. Saw no lightning and heard but little thunder. Saw no funnel appearance.



Elleot Utterback was sixty rods south of the tornado at this place. He saw the clouds come whirling. The height of the whirling clouds was about 60° and the width about 30°. Saw lightning and heard thunder once or twice. Hail followed the wind in small quantity, and rain fell in considerable amount three-quarters of an hour later. During the day the direction of the wind was southerly.

John Malcum, section 30, Lancaster Township, testified: Was one mile south of tornado when it occurred. Heard a roaring like steady thunder in the west about a quarter of an hour before the storm came. Saw no lightning. A cloud covered the west, the northern and the northeastern portion of the sky. It extended somewhat beyond the zenith. The rest of the sky was clear. Saw a whirling mass of clouds. Could distinctly see them whirl contrary to the hands of a watch. The whirling mass appeared to be about 60° high when directly opposite. A smart shower fell some time after the tornado.

On Malcum's farm, the roof of a stable was blown to the southeast. This was the first damage done by a northwest wind. Two hundred yards south of the stable a fence was blown toward the northwest and north. This was the first evidence of a destructive southeast and south wind. The storm after becoming destructive had traveled one and a half miles before it developed force sufficient to commit destruction by a northwest and southeast wind.

T. Dawson, section 31, Lancaster Township: The tornado passed directly over the farm buildings. He testified: Saw tornado approaching like two dark clouds with an intervening lighter-colored space between them. These two clouds together presented a funnel-shaped appearance; the upper end of the funnel entered the overhanging mass cloud, which covered the half of the sky and extended to the southeast a little beyond the zenith. Its lower end did not touch the earth. It whirled contrary to the hands of a watch. Its elevation appeared to be about 60°, and its width at summit 40°. Heard some thunder previous to tornado. Did not see any lightning. After the tornado there fell a few small hail and a little rain.

The breadth of fences thrown down on this farm was about sixty rods. The barns, houses, &c., were damaged. A cultivator weighing about two hundred pounds was carried or dragged 30 feet. It presented to the wind a surface of not more than 3 square feet. If it was carried, the lifting force of the wind must have been between sixty and seventy pounds per square foot. The ground showed no signs of its having been dragged.

M. Williams, lawyer, section 32, Lancaster Township, testified: Time, probably 2 p. m; it was a few minutes after 2 p. m. Watched the storm as it approached for about one hour. A cloud rose in the west, which, stretching to the northwest, presented the appearance of heavy rain. Previous to the approach of this cloud, the sky was nearly clear. The wind during the day was southerly. About twenty-five minutes after the tornado the wind was again from the southwest. The storm-cloud did not extend past the zenith to the south. Saw the funnel distinctly. It alternately lengthened and contracted, rose and fell. When it contracted, it appeared as if the narrow point over the earth was cut off, leaving the lower end broader. At times the upper end appeared to reach the overhanging clouds, and at times to be not so high. Its shape was something like  . It was of a dark-blue color when two hundred and fifty yards distant. When three hundred yards distant it subtended an angle of about The angle subtended by the top of it at that distance was about 55°. It had a zigzag motion. Half an hour previous to the tornado, there was incessant lightning in the northwest. Heard no thunder. There was no lightning in the tornado. A little rain and hail fell just before the tornado, and a smart rain-shower about twenty minutes after it. Have heard that to the northward there was a terrific storm of rain and hail accompanied with thunder and lightning. The wind was south generally during the day. As the tornado approached, the wind changed to a little east of south. Saw the dark funnel strike the ground on my farm. Saw it whirling contrary to the hands of a watch.

This witness was stationed about twenty-five yards south of the funnel when near to it. The fences were generally thrown toward the center on either side; but where the dark cloud touched they were carried away for a space sixty yards wide. Where

Digitized by Google

re the first evidence of the dark cloud touching the earth in perfect funnel-form. But s touch is yet only temporary; like a child learning to walk, its footsteps are yet certain. It proceeds with a wavy, zigzag, circular-pendulum motion. By and by its ead will make the earth tremble.

The storm traversed Jones's farm, throwing down fences, until it struck the Wolfden hool-house, which lay near its center. The school was in session when the tornado ruck it.

Richard Weller, teacher, testified that this occurred at 2.15 p. m. precisely. This ne is valuable, and I have adopted it as one of the data for calculating the velocity the storm. The school-house was moved with the children and teacher in it to the st, the north end 30 feet, the south end 20 feet. It was not overturned. The win-ws, roof, &c., were much damaged, but there were no evidences of explosive ces. The weight of the building was given by Mr. Williams as probably thirty ousand pounds. The surface exposed was 360 square feet, besides the slanting roof. e slant of the roof was about 45°. The foundation was stone. It became very dark the tornado struck. After leaving the school-house, which is situated in a slight ine-like depression, the fury of the tornado abated somewhat. Hence, although it s nearly central over the hamlet of Hayesville, the frail houses were scarcely ched.

. U. Alford, who lives a quarter of a mile south of Hayesville, saw the tornado-cloud inging round in a circle like a flock of birds, and every now and again making a dip the ground and darting up again as high as the top of a tree. Its color was very k, inclining to green. The wind, which was south before the tornado, changed to th after it. A little hail fell as the tornado passed.

ohn Stephenson, Hayesville, a little south of the center, testified: Saw no lightning; rd no thunder; considerable rain about a half an hour after the wind.

. G. Konkricht, postmaster, Hayesville, testified: Tornado passed about 2 p. m.; rly perceived the clouds whirling contrary to the hands of a watch as the storm roached; saw lightning to northwest, and north of the tornado-cloud; heard no nder.

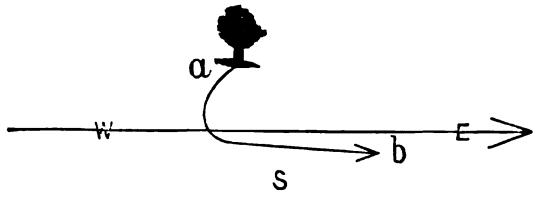
. W. Hayes, Hayesville, testified: Watched it for a half an hour previous to its val; saw two clouds, one in the southwest, and one in the northwest, which rushed ether and appeared to create a whirl; saw the clouds whirling.

. C. Dickey, who was at Hayesville, saw a cloud rush north, and then strike south h amazing rapidity; these were under-clouds; the whole northern heavens were ered with clouds; saw the funnel; it was of a dark green color and raised and ered itself at the bottom; saw no lightnings; heard no thunder.

. N. Bucher, one mile east of Hayesville, and about ten rods south of the tornado: r a funnel-shape, large at top, small at bottom, of a dark green color. It looked a kettle of soup boiling over. The funnel ended in a large cloud, which did not nd much south of the zenith. The bottom of the funnel kept bulging up and n. Wind was from the south previously. It changed to the northwest as it passed it grew cooler. At this place only a few fences were thrown down.

. H. Hawkins, Jordan farm, section 24, Lancaster Township, half a mile north of the m, and not far from widow Jacob's house, which was destroyed. Testimony: There eared at first to be two storms coming up—one from the west and the other from northwest. A little rain and hail fell before the tornado, and rain in considerable unt after it.

ne storm up to this point had been traveling east-northeast. Since leaving South ok River, it had been traversing a rolling prairie, with numerous sloughs, as they are ed, but nothing like a water-course. A little to the east of the last witness it struck ublesome Creek, the banks of which are well wooded. No sooner did it do so than creased greatly in power, changed its path temporarily to due east, and developed phenomena of two or more funnels or branches of a funnel. Down in the hollow, ng the trees, stood the house of widow Jacobs. It was completely demolished, but out signs of explosion. The storm-traces were already in great part obliterated, a new house rebuilt. The path of destruction was two hundred yards wide at point, and the general aspect of the fallen trees within this limit presented all the arances of a complete cyclone revolving contrary to the hands of a watch, ough nothing particularly worthy of notice presented itself. About a quarter of ile from the main track to the south, a swath about fifty yards wide was cut ugh the fences by a southwest wind. This swath appeared to curve toward the storm-path, but it was not possible to follow it until it reached it, because of the seness of the fences, and because there had everywhere on that side of the storm a strong southwest wind, and this swath was merely exceptionally strong.



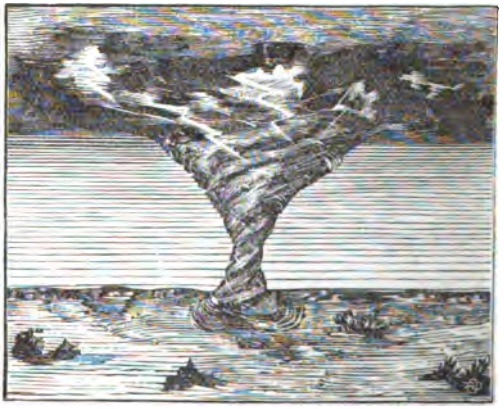
ne storm-center next traversed the Grout farm, now occupied by Samuel Brunt, passed about one hundred yards to the north of the village of Lancaster. Here perations became more interesting.

muel Brunt testified: Heard it roaring a long time before it arrived; as it ap-ched saw two funnels distinctly; their summits were lost in the overhanging

Digitized by Google

mass of dark cloud. Saw funnel on the south side, which was the smaller, sweeping around in a half circle and join the larger one. The funnel had a pendulum motion. When it struck the ground it seemed to smoke, the smoke surging up like spray from a wave-beaten rock. The wind felt cold as it passed. Saw lightning during tornado. The breadth of the dark apex of the main tornado when it touched the ground appeared to be about 100 feet. There the wheat was mown as with a scythe.

The breadth of the path of the storm of sufficient power to throw down fences was here two hundred yards. The fences on the north side were blown south, those on the south side north, while along the center everything was carried east with the storm. An apple-tree, 7 inches in diameter, which had stood on the north side of the center was carried first fourteen yards south, with a little westing, then round in a regular curve twenty-four yards toward due east, and then due east for seventy yards. A beam 2 inches by 4 inches by 14 feet, and weighing twenty-five pounds, was driven into the ground 3 feet 9 inches at an angle of 35°, after having been carried thirty-two yards from the barn-roof. The following is a sketch of the path of the apple-tree as it stood at *a* and was carried to *b*:



J. B. Jacobs, Lancaster Village, witness: Saw distinctly two whirls, the north one being the largest.

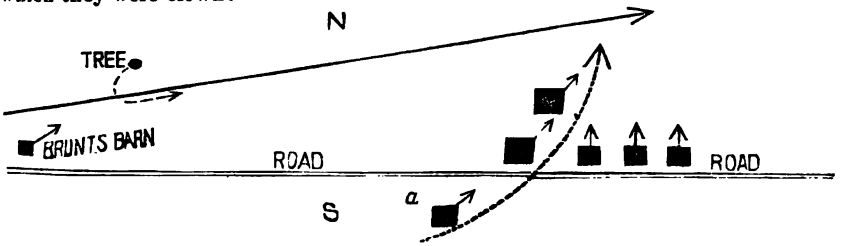
William Davis, Lancaster Village, witness: Watched for perhaps an hour previous to its arrival. Heard it for half an hour. Saw funnel when half a mile distant. The summit of it was lost in very dense clouds. It was funnel-shaped. The elevation of the summit was about 15°. It appeared to be about as high as the summit was broad. The top was twice or thrice as broad as the base. The clouds above it did not appear to whirl. Saw lightning during the tornado and heard thunder above the roar of the tornado. Previously the wind blew from the southeast strongly. After it passed it blew from the northwest. Saw boards whirling round in the funnel.

Mr. Beall, witness: Was on north side of storm, half a mile from its edge. It appeared like a funnel, and perfectly black. Saw rails whirling in it. The upper edge into which the funnel went did not whirl. It subtended an angle of 55°.

Fred. Tollman, Lancaster Village, testified: Was within the edge of the tornado. Was whirled like a top for fifty yards and lodged against a fence. Observed it for more than fifteen minutes before it came. Saw trees twisting in the grove half a mile distant. Saw the funnel whirling contrary to the sun. Its summit was lost in overhanging cloud. Thinks the upper cloud was also whirling. Saw only one funnel. Saw lightning flash up and down the funnel. Saw a tree thrown out from the top of the funnel about one foot in diameter. Top of funnel 60° high when seventy yards off. There were two funnels with the small ends together, thus, the upper one being the largest:

The above description applies to the lower one. It had before the tornado about as large as hen's eggs.

Austin Jacob, about half a mile north of the edge of the tornado. Testimony: Saw two funnels seperimposed, with the small ends together. The upper funnel was much the darker and larger.



L. W. Low, Lancaster Village: Mr. Low's house was south of the principal portion of the village, and near the center of the tornado. Testimony: Was in the house when the tornado came. The southwest corner was lifted off the ground. The floor was then driven toward the roof, and the house went to pieces. Was severely injured. Was wet and covered with mud. Felt very cold. Felt warm soon afterward. Seemed to be surrounded with a heavy mist. Saw only one funnel. Saw lightning on both sides of it.

The last witness has weak eyesight.

Digitized by Google

J. C. Jacobs, Lancaster Village: Witness was one hundred yards south of the edge. Shape was like a funnel, point up.

This completes the evidence for the village of Lancaster. It is somewhat discordant, or, rather, various. Some saw only one funnel; some two funnels, side by side; and others two funnels superimposed, with the small ends together. The discrepancies are, however, easily accounted for. As the cloud approached, it grew very dark. The tornado doubtless changed its form rapidly. The observers took a glimpse at it and ran to attend to their houses; or, as in the case of Follman, had to watch it under difficulties. Those who saw two funnels appear to have seen through the center of what appeared to those at a greater distance as only one funnel with the larger end down. The evidence afforded by the ruins in the path of the storm gives no support whatever to the belief that there were two distinct whirlwinds. The two dark clouds touching the ground worked together in the strictest harmony in producing such effects as would be produced by one tornado whirling contrary to the hands of a watch. But, as already instanced, streaks of wind of unusual power curved in half circles toward the center at certain places. One of those streaks passed in a northeasterly direction through the town of Lancaster, while the main whirl was one hundred yards to the north of it. This streak was at first only a few yards broad, but rapidly increased in width as it proceeded. It first unroofed a frail stable, without injuring the house beside it. It then increased in force, throwing down four or five houses, and unroofing as many more. The following shows the position of the houses and the directions in which they were blown:

The long arrow denotes the main track; the curved arrow the streak mentioned; the short arrows show the direction of the destructive wind which threw down the various buildings. Between the building *a* and the main storm-path there is a space of fifty yards comparatively uninjured. The sketch does not pretend to be strictly accurate as to distances, but to give the relative positions of the houses.

Leaving Lancaster, the whirlwind traveled down the declivity toward North Skunk River in a direction somewhat east of northeast. It leveled the fences in its path, in the way already described, and never varied from its commencement to its end. The house of widow Dogget, situated about a quarter of a mile south of the river, stands a little to the northwest of the storm-center, at the commencement of the level bottom-lands. Here two deep ravines, one from the south and one from the east, meet. In these ravines the storm developed enormous power, smashing up the timber terribly. The roofs of the house and barn were carried south and somewhat west. The trees on the north side of the center were thrown down toward the center, some pointing southwest and south, but the majority southeast. On the south side of the center they lay pointing northeast, north, and northwest. An oak-tree, 12 feet in circumference at the base, was broken across 12 feet from the ground. At the bottom of the narrow, steep ravine, running east and west, trees were lying just as they fell, some pointing east and some west.

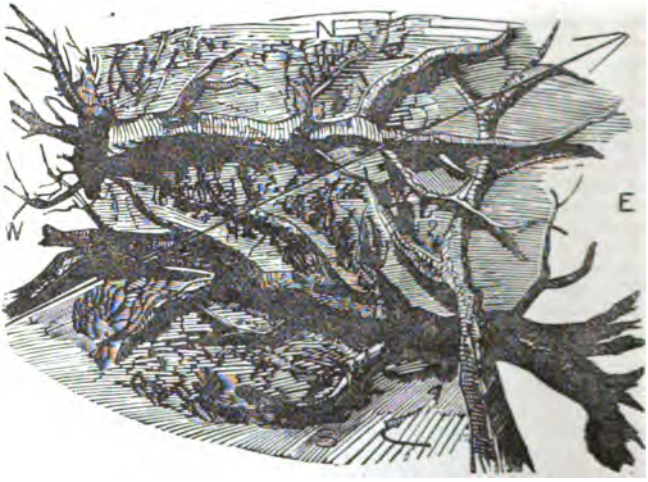
Mrs. Wimar testified: That difficulty was experienced in preventing the wind from bursting in the door and windows; that it felt cool as the storm was passing; that a few hail as large as hens' eggs fell before the hurricane, and a great deal of rain afterward; and that the point of the lightning-rod upon the barn was partially melted by a flash of lightning.

One-quarter mile beyond Mrs. Dogget's house the tornado reached North Skunk River, which it then followed for over two miles in a southeasterly direction until it came to the southerly bend of the river, opposite Kohlhaus's saw-mill, when it suddenly turned to the northeast. The bottom-lands on both sides of the river are here covered with tall timber, and through this timber the storm tore its way with resistless fury. All trees within a breadth of about one hundred yards were either overturned or broken off and barked. The barking was evidently the result of three things:

1. Many of the trees barked had been bent, so as to loosen the fibers of the wood. Such bending would infallibly loosen and perhaps break the bark.

2. The air was thick with missiles, which not only broke the bark, but sometimes

Digitized by Google



penetrated the wood. I have seen a corn-stump less than two inches in length stuck in the bark of a large tree which it had penetrated.

3. The peeling-off of such loosened and broken bark would be a light task for such tremendous blast. There was not the slightest evidence of electric action or of vapor explosion.

Broken trees had the bark torn off, both up and down, from the point of breakage. Trees half-broken and bent to the ground were similarly stripped.

At the place of rupture, the trees generally presented that broom appearance which the supporters of the theory that electricity is the principal agent in the production of tornadoes have seen conclusive evidence of its truth. It will afterward be shown, when this phenomena becomes more common than could be expected on the soft soil bordering North Skunk River, where trees were more easily uprooted than broken, that this broom appearance is due to the excessive bending and straining of the fibers of the wood, and their rupture, in succession, from the exterior inward.

The river, being impassable, rendered the examination of the general position of the fallen trees more difficult. Everything, however, corroborated the evidence already so abundantly adduced, that the tornado was a whirlwind of powerful centripetal tendency, circling contrary to the hands of a watch. The following arrangement of fallen trees was selected as being typical. It was found on the north side of the river, near the center of the tornado.

No. 1 is a tree 3 feet in diameter, but much decayed, blown down from the east-southeast. No. 2 is a tree one-half foot in diameter, blown down from south-southeast. No. 3 is a tree 2 feet in diameter, blown down from the west. No. 3 lies above No. 1 and No. 2 above No. 1. It occurred just where the storm left the river.

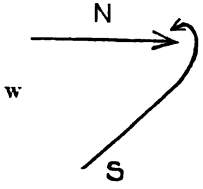
That the force of the storm was enormously increased immediately after reaching North Skunk River is proved by the greatly extended width of its path. At A. Doget's and B. C. Moore's houses, three-quarters of a mile distant from the storm-center, the out-buildings were damaged and the fences thrown down by a southerly wind. Mr. Dogget testified that the tornado appeared somewhat like two funnels with the smaller ends together, and that when apparently three and a half miles distant the column subtended an angle of about 25°. The houses of these gentlemen are situated on the summit of the bluffs facing the river, which are perhaps 200 feet high.

The house of Joseph Ash, situated on the face of the bluff, and distant from the river about half a mile, was blown to the south-southwest. Large trees were at this distance blown down in the ravines running to the river. Mr. Ash testified that the wind lasted a few minutes, and that it changed to the northwest after the passage of the tornado. A little hail fell before the storm, and a small shower of rain after it. Saw lightning and heard thunder. It grew cool as the storm passed.

Matthias Gengler's house stands on the summit of the bluff, one mile distant from the river. Due north of this farm was the saw-mill of Joseph Kohlhaus, where the tornado turned to the northeast. Mr. Gengler testified that it presented the appearance of a column rising from the river to the clouds. Its width at the top was not as great as at the bottom. It was perfectly round and perpendicular. It moved steadily along, without jumping up and down and from side to side. The angle of elevation

Digitized by Google

was 55° when opposite. The wind blew very strongly. Mrs. Gengler said that the bottom was the blackest, and that the top looked like clear, solid water. She could see it spin around and upward like a screw, contrary to the hands of a watch.



Matthias Hotel's house is a quarter of a mile east of Gengler's, and at the same distance from the river. He testified that it appeared to him like a big tower. Sometimes it was wider at the top than the bottom, and sometimes at the bottom than the top. All afternoon previous to the storm it was very dark in the north. As the tornado approached, the wind grew very high from the south, endangering the buildings. The height of the summit, when nearest, was 55° or 60°. Saw something like prairie-chickens whirling in the air; believe now they were sheep. Do not know whether any one has lost sheep.

The Black Hawk mills are situated about one and a half miles farther down the river than the point where the tornado left it.

Eli Walker, proprietor, testified that he heard a roaring for perhaps an hour previous to the arrival of the tornado. Saw it approaching apparently in a straight line for witness. It seemed to move slowly, and was perfectly steady, without any oscillating motion. Could not in the column itself recognize a whirling motion, but the light clouds around the summit of it were whirling. The top of the column had an elevation of about 30° when nearest. Saw it suddenly bend to the northeast at Kohlhaus's. Before the tornado approached the northern sky was black with clouds, which extended eastward. The south was generally clear. A hail stone or two fell as the tornado came up, and a light shower of rain afterward. Saw no lightning. Heard thunder previous to the tornado. While the whirlwind was on the river, the water ceased to flow over the dam, although the river at the time was high.

E. Stout was at Black Hawk mills. He testified: Saw it distinctly in funnel shape. Could see it as far as Lancaster from the summit of the mill-buildings. The top of it appeared, when one and a half mile distant, to be 15° in height. Saw two funnels come together and form one. The smaller one came from the south and joined the other. The top of the funnel looked like a solid body of water. Saw flashes of lightning from top of funnel, apparently northward. The small end of the funnel was up, but there was not much difference in size. The clouds above the funnel appeared to be whirling and approaching the center. The funnel which came from the south was of a lighter color than the other. The wind changed as the tornado advanced, and blew strongly toward it. The clouds above the narrow top of the funnel appeared to whirl in funnel form, with the wide end upward.

The following represents the apparent direction of motion of the two funnels as they approached each other:

Henry Lundy was at Black Hawk mills. He testified that he saw it whirling contrary to the hands of a watch. Thought he could see the top of it, and that it did not reach the clouds.

Matthias Bevens was one mile southwest of the storm. He testified that the column resembled very black coal-smoke, and went right from the ground to the clouds. It whirled with great rapidity contrary to the hands of a watch, rising at the same time like the spirals of a revolving screw. The top of it was about three times the size of the base. Little dark clouds appeared to fly out and around the dark column. When one mile distant, it subtended an angle of 30°. Saw no lightning; heard no thunder.

The house and steam saw-mill of Joseph Kohlhaus stood directly in the path of the meteor, at the distance of a quarter of a mile from the river, on the north side.

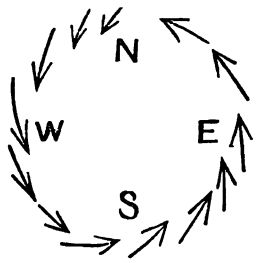
Mr. Kohlhaus testified as follows: The tornado appeared to stand still for several moments at the bend of the river, and then all at once bounded forward to the house. While standing still, it seemed to shoot or grasp out first on the one side and then on the other, as if discharges of artillery were taking place on these sides. The roaring was terrific. It resembled the sounds of machinery magnified a million times. It was a combined woo-oo-oo and whirr-r-r-r. Watched the column as it approached. It was funnel-shaped, but changed its appearance. It twisted around and up like a screw. Could not recognize bodies in the column; it was too black, and when the funnel came near it grew as dark as midnight. All the clouds were very low. They did not all revolve. Saw lightning before the storm.

The building stood upon the summit of a rising ground, about thirty feet high. Between it and the river is a half pool, half marsh. It was completely emptied of water. The breadth of the path of wholesale destruction was, upon the summit of the hill, two hundred and seventy yards. The house stood one hundred yards from the eastern and one hundred and seventy yards from the western extremity of this path. The timbers and contents of this house were carried in a half-circle first to the northwest, then to the west, then southwest, then south, and finally to the northeast, the heavier articles being generally sifted out first, thus marking the way the ruins went.

On the eastern edge of the path was an orchard, and on the western a wood. The trees in the orchard were blown down from the southeast and south; the trees in the

Digitized by Google

wood from the north and northwest. Portions of the clothing from the house, shingles from the roof lay among the trees in the wood, or stuck among the branches. There were no signs of explosion, the doors and windows having been blown in. The inmates were all more or less injured. The width over which fences were blown down was here about three-quarters of a mile. An iron plow, weighing two hundred pounds, was carried forty yards. The sheet-iron chimney was carried two miles to the northeast. An iron sausage-machine, six inches by eight, and weighing fifteen pounds, was blown away. Part of it was found twelve hundred yards distant. The wheels of wagons were smashed, and the tires twisted.



[The cut on page 1055 is a representation of the effects of the whirlwind at this place.]

After leaving the mill, the storm ascended a hill some 200 feet in height, leveling fences, but with evidently diminished violence.

Peter Randolph, about two hundred yards distant from its northern edge, distinctly saw it whirling contrary to the hands of a watch. Lightning struck a tree on his farm about half an hour before the tornado. This tree I saw myself. There was a light shower of rain after the tornado.

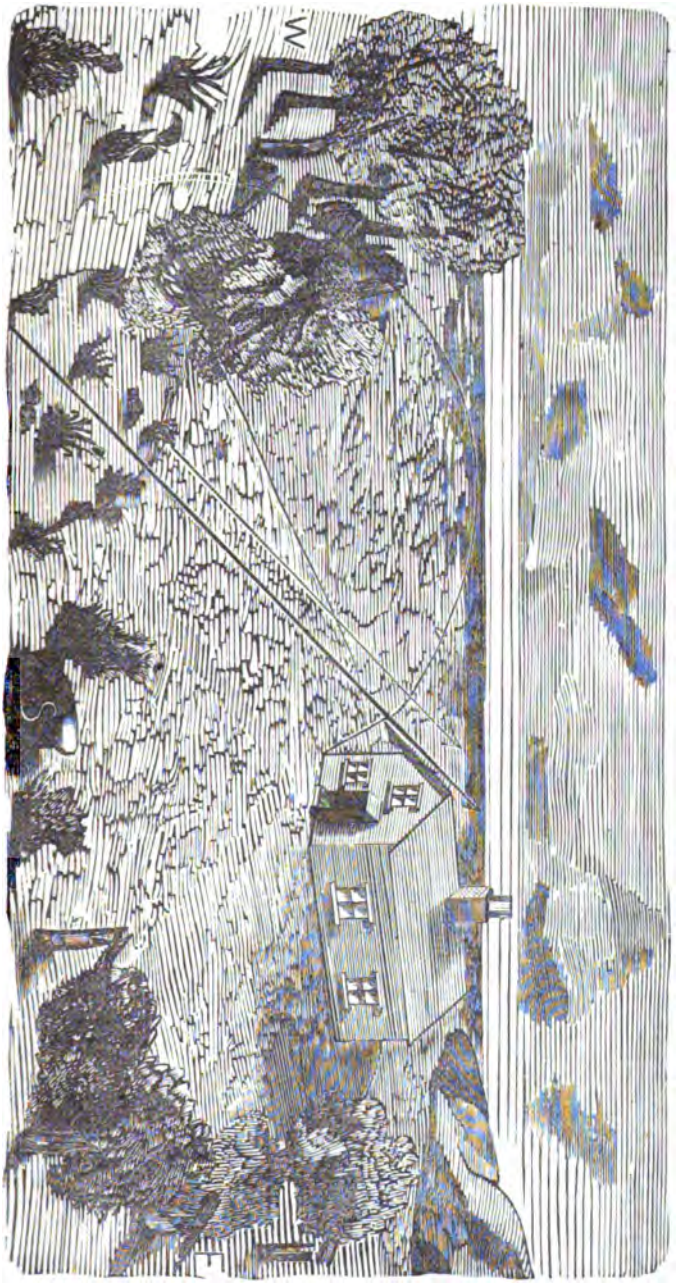
John Wehr said it looked like the cylinder of a threshing-machine, and spun around like a screw.

Passing over the top of the hill in a northeast direction, it struck Rock Creek, which here runs south, with a little easting. Immediately altering its course, it went straight up the creek for about half a mile, developing prodigious power. The large trees which lined the banks were torn and peeled and overthrown in promiscuous ruin. At a point where there is a small circular island, and a considerable amount of stagnant water around, the storm would appear to have stood still for a moment. The following sketch shows the position of the fallen trees at this point:

There were no trees on the island itself. There was no evidence whatsoever that the barking of the trees had been effected by electrical action or sudden evaporation. Everything tended to prove that the bark had been loosened and broken by the excessive bending of the trees and by flying missiles. One of the steers killed at the creek had an oak rail driven completely through its shoulders.

On reaching a slough which enters Rock Creek from the northeast the tornado followed it. Beside this slough and close to the creek was a small grove of young trees belonging to John Stein. This grove was completely carried away, nothing remaining, except a few barkless trees. At no point in its course did the storm develop greater energy than at this grove. Here generally young saplings, over which the center of the storm passed, were, although stripped of bark and twigs, left standing. Here the ground was whipped as bare as though the grove had been lashed with a whirlwind of fire. The tornado then passed between the houses of William Goeldern and John Stein, sweeping the fields, within the narrow path of its greatest violence, clean of grass, wheat, and corn-stumps, while the ground was torn and furrowed by flying rails and trees. The rails and broken timber had been gathered from the fields; but John Stein assured me that they lay thickest about the center of the storm. Along the sides of the path of greatest violence, many rails were driven deeply into the soil, end foremost.

While the main whirlwind thus pursued the path described, there were smaller shoots or arms which played havoc on its southeast side. Such an arm cut a swath about twelve yards wide through Schild's orchard from southwest to northeast, the swath widening as it went. It was not possible to trace it until it reached the main storm, for reasons similar to those already given. It seems probable, however, that it joined it at the little island above mentioned, where the storm appears to have momentarily stood still. The relative positions favor such a surmise. This strong southwest wind was a quarter of a mile distant from the center of the tornado.



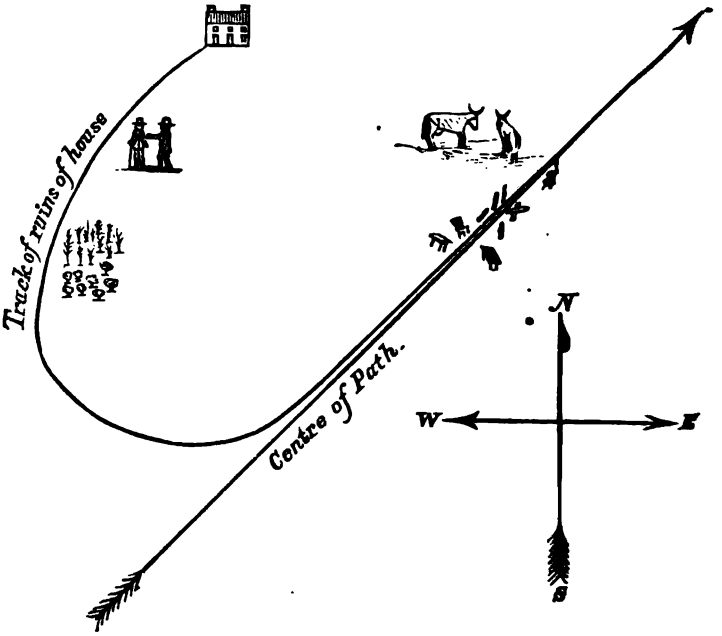
A similar streak leveled the fences close to the house of John Stein for a width of fifty yards, while nearer the main tornado the fences remained standing. This streak, I surmise, joined the main storm at the grove above mentioned. A similar arm struck down the new barn of F. A. Latz, about a quarter of a mile farther on, without touching weaker buildings close beside it. The path of this streak is said to have been quite distinct among the fences until it joined the whirlwind near the house of Peter Miller. The fences were, however, already restored.

George Starr, three-quarters of a mile southeast of the tornado, witness: About 5 it commenced to thunder and lightning in the northwest. The storm advanced from the northern sky, and it lightened terribly there previously to the arrival of the tornado. A big cloud extended from southwest to northeast. It cleared up immed-

Digitized by Google

fter the tornado, both here and in the north. Lost eighteen head of cattle at Rock reek. One was perforated by a rail.

John Marsh's house stood a little to the northwest of the center of the storm. His



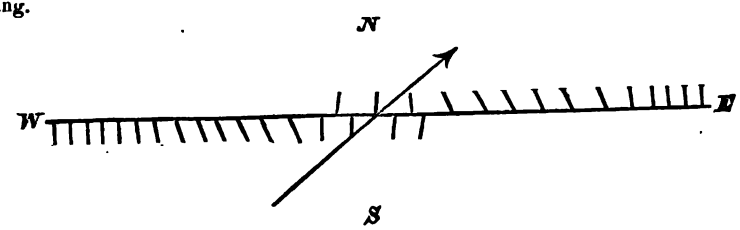
Effects of the whirlwind at the house of Joseph Kohlhaus.

mony: Watched it as it came directly toward me. It deflected a little from side de, with a zigzag motion. It turned and twisted like a screw in revolution. All family were in the house, the house having no cellar. It became as dark as mid-

Digitized by Google

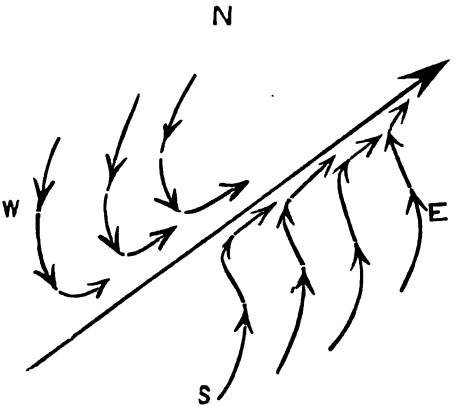
night. The windows and doors were blown in, in spite of our resistance, and we knew no more until we found ourselves lying in the slough severely wounded.

The destruction at this house was most complete. The house was carried forward from its foundations bodily; but as it was going down a declivity toward a slough, failed to strike the ground until it went to pieces. The heaviest timbers and the habitants were deposited in a slough, about one hundred yards south-southwest where the house stood. One child was killed instantly, and Mrs. Marsh has since died. The fragments of the house were carried, as was easy to trace, first to the southwest, then in a curve to the south, the southeast, the east, and then along the center of the storm to the northeast, the heavier articles sifting out as they went. I found ears of corn two hundred yards to the southwest and south of the house, and a fragment of heavy wood four hundred yards to south-southwest. Two cows and thirteen hogs were in a yard a little nearer the center of the storm than the house. They were carried one hundred yards to the southeast, and killed or fatally injured. A stone from the foundations of the house, weighing about one hundred pounds, was said to have been carried about one hundred yards south; but I could not find it. Sewing-machines, cultivators, wagons, &c., were wholly carried away, and left not a wreck behind. The timber was generally reduced to the dimensions of fine fire-wood, and thickly strewn along the path of the storm to the northeast. The width over which fences were thrown down was here about a half a mile.



Sketch of the path of the ruins of Marsh's house.

A quarter of a mile to the north of Marsh's house stood the house, barn, &c., of W. Fuh. They were blown to the southwest, but without being carried away. The first house struck was that of M. E. Harris, the storm-center passing about twenty yards to the northwest of it. The fiercest of the storm was here only one hundred yards wide, but fences were blown down for over five hundred yards. The doors and windows of the house were driven in by the wind and the flying missiles, and immediately the house went to pieces. The house and out-houses were carried away, broken to small pieces, and deposited for a mile or two along the path of the storm. The trees around the house, which were not plucked out by the roots, had their tops and branches broken off and their bark stripped from them. The stripping of the bark was evidently due to the causes already assigned. The stripping was most complete on the southwest side of the trees. A fence four hundred yards in length, and running north and west, was deprived of its boards, the posts still remaining in the ground. When the storm-center crossed it, the direction toward which the posts were leaning



Digitized by Google

indeterminate. On the west of the center the posts were leaning south, with a little easting, and on the east of the storm-center they were leaning north, with a little westing.

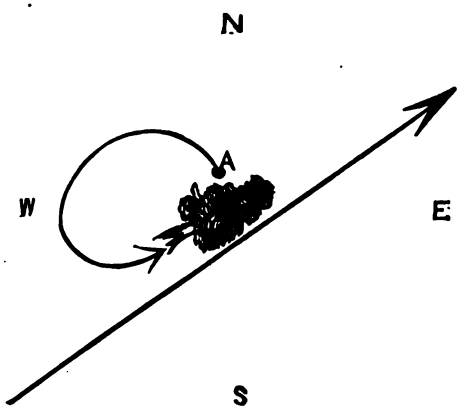
The above is something like the disposition of the posts along the line of the fence. The length of fence thrown down east of the center was about one-quarter greater than that thrown down on the west of it.

The corn-stalks in a contiguous corn-field were thus disposed: Those on the southeast side of the center curved around from pointing nearly due north to nearly due west. Those on the northwest side curved around from pointing nearly due south to nearly due east. Along the center all pointed with the storm. This shows the direction of the last wind, strong enough to alter the position of the stalks.

Corn-field.

Matthias Linen, a quarter of a mile northwest of the edge of the storm, testified that it presented the appearance of a great column, reaching from the ground to the clouds, and whirling contrary to the sun. It seemed to remain almost still at some places, and then would dart forward. Hail four inches in diameter fell as the storm passed. They were very irregular in form.

Paul Ritter, Clear Creek Township, section 9, testified that the tornado looked like a big tree, only it was five times greater at the top than the bottom. It turned like a wheel in a mill. Its direction of evolution was against the hands of a watch. At the distance of a mile, its top, when it entered the cloud, made an angle of about 60°. Hail as large as pigeon's eggs fell before the storm, and it rained very hard after it. Saw lightning in the west previously.



Mr. Ritter's house stands about seventy yards to the northwest of the storm-center. Its path is here about two hundred yards wide. The arrangement of stalks in a corn-field was the same as that already given. The roof of the house was carried south. A stump-cutter, which was standing by the house, was carried—the iron portion fifty yards south, the wooden portion half a mile to east-southeast. Wheels which came within the reach of the storm were dashed to pieces, and the tires twisted into all sorts of shapes. An oak tree, 3 inches in diameter, and which stood exactly in the storm-center, was split by a fragment of a board one inch thick. The board was originally probably 6 inches broad and 8 feet long. Of the two small fragments remaining in the tree, the longer was only 17 inches in length. The board was driven into the tree from the southwest. The path of extreme violence, about fifty yards wide, was strongly marked in the grove of young oaks. They looked as if they had first been lashed against a pile of stones and then trailed in the mud. Portions of bark were struck off and the smaller branches shattered and peeled. This grove stands upon the edge of a steep declivity about 100 feet in height, at the bottom of which flows Clear Creek. Here is a circular hollow nearly enclosed by high bluffs, and within it the storm raged with demoniac fury, smashing trees of 4 feet in diameter to pieces.

The following instance was found on the opposite declivity, up which the storm raved with undiminished power:

The tree stood at A originally. Its root was partly decayed, and it must have fallen with the first strong gust. The path which it traveled was cut out in the grass by its root. This path was forty-seven yards in length and was nearly circular. It first moved to the northwest and then round in a curve, until it lay pointing to the northeast, with its top almost touching the spot where its root had formerly been. The tree stood to the northwest of the storm-center, and was two feet in diameter.

Digitized by Google

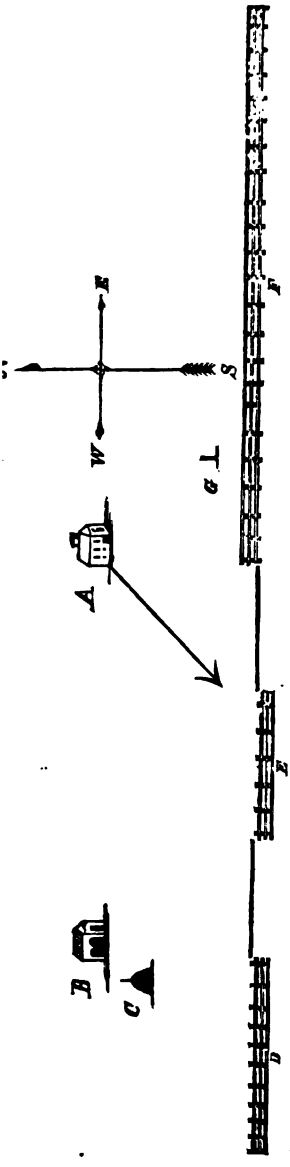
Crossing the summit of the rising ground, which was thoroughly plowed up, the storm traversed a wooded ravine, where for a width of fifty yards it deprived the young trees of their twigs and of much of their bark, besides throwing down the full-grown.

Nick. Engledinger, section 10, Clear Creek Township. His house stood about one hundred yards from the southeast edge of the tornado. From any indications which the remains presented, the timbers must have first been carried north. Two persons were killed—one of them being torn to pieces. A hog weighing four hundred pounds was carried one mile and a quarter in the line of the storm.

The house of Jacob Koerth stood fifty yards within the northwest edge of the storm. The timbers went south. The people tried to prevent the wind from blowing in the doors and windows, and could not. The wind entered and blew the house asunder, leaving the floor in its proper position. Hogs weighing three hundred pounds were carried to the northeast across a ravine and deposited three hundred yards away. A horse, a cow, and a bull were similarly carried two hundred yards. Sheep were carried four hundred yards. In addition to the accidents inseparable from such an aerial voyage, the bodies of the animals were driven full of pieces of wood. On this account, the bodies of all animals which perished in the storm were burned.

A horse-power machine, partly wood, but chiefly iron, and weighing two thousand four hundred pounds, was pushed or carried six yards. It was resting on the ground, and was separate from all other objects. There were no marks upon it arising from violent collision with other bodies. It exposed a surface of about two square feet to the wind. It lay close to the ground. The master of this house was absent, and information, owing to the invalid condition of the inmates, was hard to obtain.

The storm now turned somewhat more to the northward, traversed several fields demolishing the fences, until it struck the house of R. F. Campbell, Lafayette Township, on the borders of Clear Creek Township. The exact position of this and the two immediately preceding houses was difficult to determine upon the map, because of its very defective condition, and because their owners could not tell me what section they were in.



Mr. Campbell testified: That previous to the tornado he observed several currents above one another among the clouds. The wind was from the southeast. The lower current of clouds from the southwest, the next from the northwest, and the highest from the northeast. It commenced hailing about fifteen minutes before the storm. The hail was, in some instances, three inches in diameter, and fell in considerable

Digitized by Google

quantity. It was calm when the hail fell. The hail was very cold. When two were put together they immediately froze. The north was full of black clouds previous to the tornado, in which the lightning flashed incessantly. Heard a dull, thundering noise in the northwest previous to the tornado as of falling hail. There appeared to be rain or hail falling on both sides of the vortex as it approached.

The preceding cut shows the appearance it presented at the distance of seventy yards. There appears to be two incipient funnels, one on each side:

A post 8 feet in length and 4 inches in diameter, and driven into the soil 3½ feet, was pulled out by the wind. It stood without attachment.

The width of the storm here is one hundred and sixty yards. The house stood within twenty yards of the northwest edge. It was tilted up on its corner bodily, inmates, floor and all, and deposited on its roof seventeen yards to the southwest of its former position, and then went to pieces. There was no indication of explosion. The accompanying is a plan of the effects of the storm at this house:

A is the house, which was carried in the direction of the arrow. B is a stable and C a haystack, both untouched. These were twenty yards from the house. D, E, and F are portions of a fence which were thrown down. D and E were thrown south, leaving the intervening portions untouched. F was thrown north. G is the post already mentioned.

This was the last destruction in Keokuk County. The tornado ceased to touch the earth on Mr. Campbell's farm. It drew itself up into the cloud from which it had come down. Hitherto it had traversed a country full of deep and well-wooded ravines. Here it entered upon a flat, bare country, in fact a watershed. It continues much the same for the seven miles which the tornado here skipped.

J. Yeats Brockway's farm, Lafayette Township, witness: Saw whirling in the clouds, after the tornado lifted, contrary to the hands of a watch. Watched it for ten minutes at least afterward, and it continued to whirl. The whirling portion of the clouds did not appear to be wide.

Mrs. Fobes, who resides about one mile northwest of the line of the tornado, witness: Saw the funnel. It seemed to stand still. Then it took a bend to the east. Then it grew so dark she could not see it. It grew lighter, and she could see it distinctly to the northeast of Campbell's house. It vanished suddenly, and she saw it whirling at a furious rate in the clouds contrary to the hands of a watch. Did not notice any more roaring after the tornado lifted.

H. Case: Resides about one and a half miles from the line of tornado had it continued. It rumbled a long time before the tornado. The sky was clear in the southeast. Saw no lightning. Hail of large size fell before the tornado approached. The center of the hail was shaped like a bird's egg, and pieces of transparent ice—like rock-candy—were stuck all around it. There was scarcely any rain afterward. The wind was blowing from the southwest at first and changed to the east as the storm came near.

Katie McLoud, school-teacher, witness: The school is a little to the northwest of the line of the tornado had it continued. It must have been about 3 p. m. when the tornado was here. Distinctly saw the funnel whirling contrary to the hands of a watch. Watched it until I could not see it for heavy rain. It had hailed about half an hour previously. The wind, while it rained, came from the northeast, blowing nearly straight toward the storm.

. H. Simpkins, Keota, witness: Thinks the sound continued after the tornado d, but not so loud.

oseph Charlton, Keota, witness: Saw the funnel distinctly reaching from the earth he clouds. The clouds were very low. Saw the tornado disappear. It had only

Digitized by Google

to rise a little way when nothing, except the low cloud, was visible. The dense low clouds continued the same and the funnel only disappeared. The southern sky was clear.

J. R. Turner, Keota, witness: There was a very heavy rain, mixed with enormous hail. One hailstone was 7¾ inches in circumference, after lying some time.

T. D. Melville, Keota, witness: It commenced to hail about twenty minutes before the tornado disappeared. Further to the north it commenced sooner. The low cloud allowed only a small portion of the tornado to be seen. At three miles distance the funnel only subtended an angle of 15°. The rain came about twenty minutes after the hail. Weighed a hailstone of four and a half ounces, measuring 3 inches in diameter. It lightened a little.

T. N. Smock, Keota, witness: It hailed before the tornado disappeared. Saw some lightning in the direction of the tornado. The direction of the wind, while the hail was falling, was from the northeast; but it was light. There was not much wind with the rain afterward.

G W. Erwin, Keota, witness: Remembers that when the tornado lifted the sound ceased.

W. R. Charlton, Keota, witness: Did not not notice the noise after the tornado lifted. Heard it long and loudly before.

Robert Renfrew, Keota, witness: The town was all scattered with oak-leaves as the tornado passed. The wind previously was southwest. It changed to east as the tornado approached, and during the east wind the oak-leaves fell. After the oak-leaves fell, the sound suddenly diminished. Saw an elm fence-board 8 feet by 6 inches by 1 inch, and weighing from fifteen to twenty pounds, taken out of the ground. It was driven about 4 feet into the soil at an angle of about 45°.

Dr. D. McFarlane, Keota, witness: Was five miles on the southeast side of the line of the tornado had it continued. Heard in the west a roaring for perhaps twenty minutes previous to and after seeing a smoky appearance.

J. F. Wilson, postmaster, Keota, witness: About 3 p. m. was making up the mail. The storm was then coming up.

The storm having ceased to act as a tornado upon the surface of the earth, I proceeded to Westchester, Washington County, where it was reported to have struck. There can be no doubt, however, that a strong, though not a destructive wind, was felt over the intervening space, and that it obeyed the usual law of cyclones by blowing in spirals toward the point over which clouds continued to whirl like a great wheel.

G. W. James, station agent, Westchester, witness: Saw the main cloud whirling rapidly contrary to the hands of a watch. Saw an arm come down and strike the plowed field. Could hear roaring overhead. The roaring was louder before the storm arrived then when it was here. A few large hail fell and a little rain.

J. T. Robertson, Westchester, witness: The arm which came down carried up considerable quantities of mud and cornstalks. A few fences were blown down and a small wooden building damaged. There were only a few gusts. The revolving cloud was only a little way above the tops of the houses.

Mrs. Thomas Gavin, Westchester, witness: The wind blew down the blacksmith's shop in the rear of our house. The house itself was shaking. Hail fell as large as hens' eggs. It grew quite dark when the house was struck. Everything was blown toward the northeast.

S. W. Wilson Cedar Township, three-quarters of a mile northwest of Calvin Craven's farm: Heard roaring for more than an hour previous to the advent of the tornado Watched the cloud as it came along. Saw the tree-tops whirled by it. It appeared to be only 10 feet above the tree-tops. Hail as large as pigeons' eggs fell previous to the tornado, and a great quantity of rain after it.

T. B. Coffman, Cedar Township, section 33: (The tornado passed about a quarter of a mile southeast from witness.) Heard roaring like a heavy train of cars. Saw a whirling cloud in shape of a funnel. Hail not so large as hens' eggs fell immediately after the tornado passed. The top of the funnel was about 40° high when it was nearest.

Rev. J. P. Coffman, Cedar Township, section 33, witness: The tornado arrived about 3 p. m. Heard the noise for more than one hour previously. When it was hailing heard the sound just as distinct as before. Did not hear roaring after the storm passed. The wind before the storm was nearly due south. After the storm, and with the rain, the wind came from the north and northwest. Have learned that two or three miles to the north the rain was tremendous. There was lightning in the northwest previous to the tornado. As it approached, saw light, fog-like clouds, rushing, with the greatest rapidity, from the north. Its form was not so distinct before as after it passed, when it presented a decided funnel appearance. It was nearly clear in the south. When the funnel was distant about one mile it appeared to subtend an angle of about 25°. The funnel might have entered the dark, overhanging clouds, but it appeared to be wholly in view. There seemed at one time as if

Digitized by Google

there had been a violent explosion in the revolving mass, as it was somewhat broken up. Hail larger than pigeons' eggs fell with the south wind before the storm.

The tornado passed over Mr. Coffman's house, blowing down fences about a quarter of a mile in width, and damaging buildings. It was all done by a southwest wind.

Calvin Craven, Cedar Township, section 33, witness: Previous to the storm the wind blew briskly toward it from the east. The cloud, as it approached, extended from southwest to northeast, covering the whole northern sky. Heard the roaring of the tornado, like several trains in motion, about thirty minutes previous. Saw white, foggy clouds darting through one another with frightful velocity as it came near. Above these whirling clouds was a dense black cloud. A few hail fell before the tornado, and a little rain after. Have heard that a most tremendous rain fell about one mile and a half to the north. It was extremely warm before the storm.

J. C. Brown, Jackson Township, witness: Was on the northeast of Calvin Craven's. Noticed the tornado first as it was tearing his fences, &c. At this time there was one whirl which reached the earth. It was not a jet black, but the color of coal-smoke. There was a big cloud directly over, but, although in commotion, it did not whirl. Went into a ditch to escape the hurricane. I then saw other two funnels, one on the south side and the other on the north side of the main one. All three moved forward toward me; but the outside ones also moved toward the central one. In a short time they joined the central one, which then appeared to stand still, and whirl around and around for a moment. The side ones did not whirl. They were bent forward at their lower ends where they touched the ground. The middle one did not whirl. It moved due east, and then northeast, and then due east again. The tops of all these were several times wider than the lower portions. Saw no lightning. A little hail fell before and a little rain after. The wind blew from the southeast before and from the north-northwest after the tornado.

William Scranton, Cedar Township, section 27: Scranton's house stands on the northeast edge of the storm. The roof of the barn was carried 150 feet due east. A tree in the orchard was blown toward east-northeast. The center of the storm passed over the center of the farm. The fences on both sides of it were thrown down toward it. The width of the path here is half a mile. The storm appeared to Mr. Scranton like two clouds coming together, one from the southwest and the other from the northwest.

R. H. Craven, Cedar Township, section 27, witness: A little hail fell before the tornado, and a little rain after it. The wind was northwest when the rain was falling. It cleared up about half an hour after the rain. In two places on the road east of Scranton's house ten to fifteen rods of fence were blown down, leaving the intervening fence standing. The fences on this farm were blown as usual.

W. H. Burham, Cedar Township, witness: Was on the edge of Scranton's farm. Heard the storm a long time before it came. Saw it about twenty minutes. The wind before the storm came from the south quite strong. Then it grew calm. Then there came a very hard wind right from the north. An intensely black cloud, apparently about 4 feet wide at the bottom, and swelling out like a large haystack, passed three hundred yards to the south. The top of it, when it entered the clouds, appeared to be about 45° high. It moved up and down, now striking the ground, and now passing over it. When it struck the ground it tore up everything. Saw it whirling contrary to the sun. Hail as large as walnuts fell before the storm, and a hard rain-shower after it, and then it cleared up immediately. Heard there was a heavy rain two miles to the north, washing away culverts and bridges. It felt cool as the storm passed, but grew very warm afterward. Saw rails flying out from the summit. An average rail weighs about forty pounds.

Frank Brown, Cedar Township, section 26, witness: Distinctly saw the funnel revolving contrary to the hands of a watch. Its height at one and a half miles distance was about 15°. Its top was five times broader than the lower end. Saw it strike the ground after it passed. Dark clouds appeared to strike the ground and rebound like spray. Saw only one funnel. The cloud extended from southwest to northeast, covering the whole northern sky. Observed sheet-lightning in the tornado several times. It grew slightly cold as the storm passed. When the tornado had passed about one and a half miles it appeared to stand still, and a strong gale, with rain, blew directly from it, so that I thought the storm was coming back. Almost everything on the farm which was blown down was blown toward the northeast. The breadth of path is a quarter of a mile.

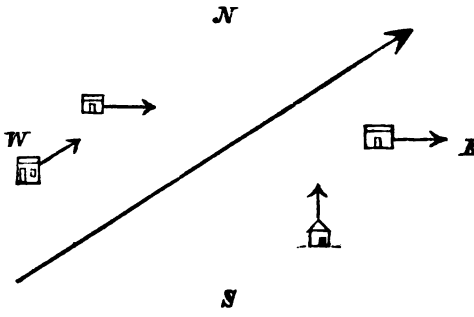
Mr. Brown's house stands on the southeast edge of the storm.

J. S. Philips, Cedar Township, section 26, witness: Was holding the window looking west to prevent it from being blown in, and noticed that it was 3.15 p. m. Hail fell, between a tea-cup and a hen's egg in size.

Mr. Philips's house is one-half of a mile southeast of the storm-center.

W. W. Cook, Cedar Township, section 25, witness: (House four hundred yards southeast of the edge of the storm-path.) About twenty minutes before the storm came up the wind blew briskly from the south. When the tornado was passing it blew a strong

Digitized by Google



gale from the southwest. It rained after the tornado, and during the rain the wind blew from the west.

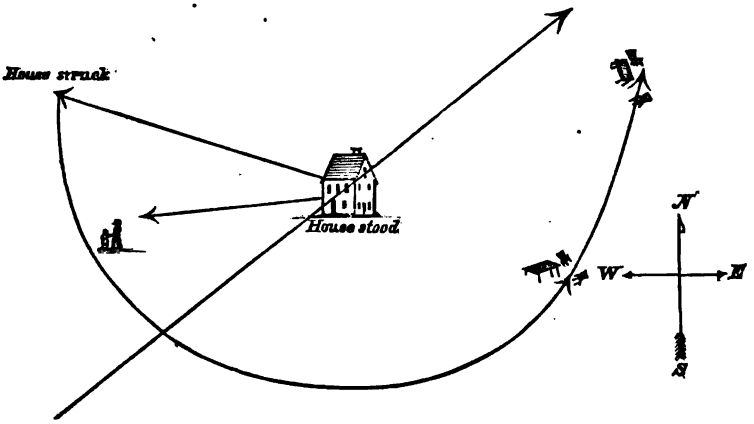
The son of this witness was two miles to the southeast during the storm. Hail as large as pigeons' eggs fell there and a little rain.

J. W. Plumber, Cedar Township, section 26: (House on southeast edge of the storm. When the tornado was several miles off saw a mass of clouds come from the northwest and another from the southwest, and rush together. The angle between the southern limit of the southwest clouds and the northern limit of the northwest clouds, when several miles distant, was about 45°. The angle of elevation was about 35°. Beside these underclouds, there were overhanging masses of cloud. Saw the funnel-form distinctly after the storm passed. It appeared to be twice as broad at the top as the bottom. It looked like a screw turning contrary to the hands of a watch. When three-quarters of a mile distant, it subtended an angle of 25°. Hail fell about half an hour before the storm, with a gentle east wind. When the storm had approached within half a mile, the wind came so strongly from the south as to blow a man off his feet. It rained a little some few minutes after it passed, with a west wind. About twenty minutes after the tornado, a light shower fell, accompanied with a northwest wind of about twenty-five miles per hour. Saw lightning in the northwest before the storm.

John Maughlin, Cedar Township, section 25: The storm-center passed right over Mr. Maughlin's house. He testified that he saw a complete funnel-form about two hundred yards distant, and that it went up into an overhanging mass of cloud. The funnel was perfectly opaque, and left a fog behind it so that nothing could be seen for several moments after it passed. At the distance of two hundred yards, it appeared to be only 15° in height. Saw no lightning.

The outhouses on this farm were badly damaged. The accompanying sketch shows the position of the ruins. The arrows point in the direction toward which the buildings were blown down. The fences were blown toward the storm-center. Those at the center were carried away.

Andrew McKee, Cedar Township, section 30, witness: The time was 3.10 p. m., precisely. The clock, which had just been cleaned and regulated, was thrown down and stopped at 3.10 p. m. Previous to the tornado, the lightning was warping incessantly like a snake among the dark-blue clouds in the northwest. Chunks of ice about one inch in diameter fell previous to the tornado, accompanied by a light east wind.



I, myself, saw the clock above mentioned. It still pointed to 3.10 p. m. Mr. McKee's house stands fifty yards within the northwest limit of the storm-path. The buildings were partly pushed, partly blown down toward the south-southeast. The fences were blown to the southeast. A little empty house about forty yards to the east was blown to the southeast, and some of it was carried clear across the path of the storm.

The hedges along the east and west road are here filled full of *débris*, such as corn-stumps, &c. On the southeast of the storm-center the *débris* is driven into the hedge from the south, and on the northwest side from the north, but there is a greater extent of hedge with *débris* driven into it from the south than from the north. The portion of the *débris* driven in from the north seems frequently to have been subsequently affected by a west wind. The hedges running north and south have *débris* driven into them on the north of the center from the east, and on the south of the center from the west, but the extent of hedge with *débris* driven into it from the west is greater than that with *debris* driven into it from the east. The hedges over which the storm passed looked as if they had been whipped violently against a wall, and then trailed in the mud. They were smashed and partially barked, and sometimes carried away. This description applies to the hedges over which the whirlwind passed at any part of its course.

George Gilchrist, Cedar Township, section 29, (house directly in the center of the storm-track,) witness: When the storm struck the house Mrs. Gilchrist, a boy, and a child were in front of the west door trying to reach the cave, the boy and child being a step or two in advance. The boy and child were instantly carried several rods to the west, while Mrs. Gilchrist was thrust back into the house. The house immediately went bodily, going a little to the north of the west, who saw it go past like the railroad, as he expressed it. Its sills struck the ground forty yards from their former position and the house tumbled over and went to pieces, leaving the inmates comparatively unhurt. As it went to pieces it was struck by a west and southwest wind, the furniture being carried far to the east and northeast. It grew dark as midnight when the tornado struck.

Digitized by Google

William Caldwell, Cedar Township, section 29, witness: When the storm struck the house the inmates were in the kitchen, which was a separate building. The wind blew so hard as to threaten to blow in the south door. Four strong men placed them-

Sketch of effect of storm at Gilchrist's house.

selves against it. The hinges and lock were partly broken. These four men barely held the door with their utmost strength until the house went in a body. The men found themselves, together with the other inmates, a few yards to the north, lying among *débris*. The door was found a quarter of a mile away. It presented to the wind an area of 18 square feet.

Mr. Caldwell's house stood on the southeast edge of the most violent vortex. It was first pushed 6 feet to the northwest, plowing up the ground. The resistance of the ground and of tree-roots here stopped it. It then turned up on its edge, and was lifted over the tops of trees 20 feet high, without injuring them, and carried 100 feet to the northeast, falling entire, and going to pieces as it fell. The house stood with its end to the south. The area of this end was 280 square feet or thereabout. The area of the floor of the house was 480 square feet or thereabout. The weight of the house could not have been less than twenty tons. The trees over which the house was carried are young, and were probably so bent as to allow the house to rise at an angle of 45°.

A heifer, weighing seven hundred pounds, was carried away by the wind, and thrust head foremost into wet soil until her forequarters were buried.

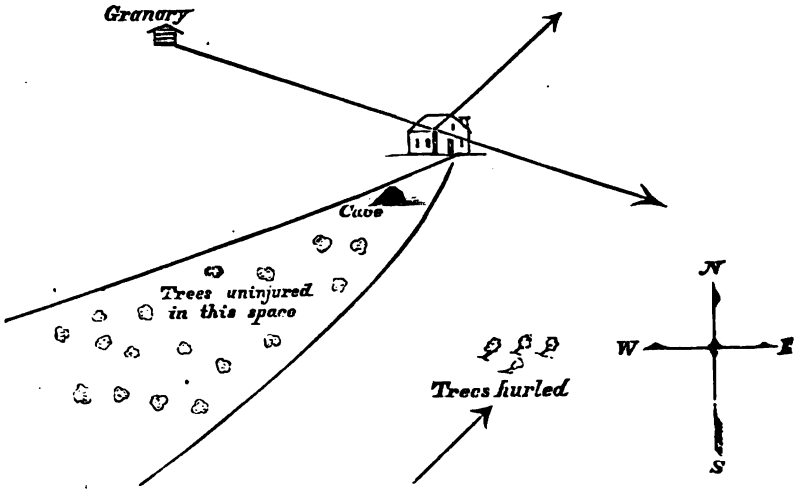
R. M. Stevenson, Jackson Township, section 25, witness: The wind blew from the southeast as the storm came up, changing to north as it passed. The rain came with the north wind. Saw the funnel make two dips and touch the ground. The top of the tornado, when seven hundred yards distant, appeared at an angle of 35°.

The house of this witness stood a quarter of a mile southeast from the center of the storm. The outbuildings were somewhat damaged.

T. P. Harbaugh, Cedar Township, section 13, about one mile from edge of storm, testified: That he saw it go straight forward without stopping. Saw it rising and falling.

A. Booth, Cedar Township, half a mile northwest of storm: Saw it twenty or thirty rods northeast of Frank Brown's. Saw it whirling against the sun. The wind came from the east before the storm and from the northwest after it.

R. Finney was on the northwest side of the center, about one mile distant. He testified: When it was directly opposite, it appeared to reach up to the clouds. It subtended in width an angle of about 35°. In height it appeared to subtend an angle of about 40°. The bottom of the funnel was perfectly black. When it struck a house, could not see the house. Thinks it was lighter a little way up. Could see a roof carried up and fly to pieces. About fifteen minutes before the storm it hailed a little, and it rained for ten or fifteen minutes after. The wind, when the hail was falling, was from the northeast.



John Gordon, Cedar Township, section 25, one-half mile southeast of the center: It hailed about half an hour previous, with a southeast wind. The wind was from the west, as the tornado was opposite. No lightning was seen.

Laurie B. Mauck, teacher at Prairie Flower school, witness: Called in the children at 3 p. m. The tornado was opposite certainly not later than ten minutes afterwards.

Thomas Waters, Jackson Township, section 19, witness: Saw the tornado coming rolling on the ground like a wave. Went to the cave and called upon Mrs. Waters to follow. She would not. Stood in the mouth of the cave, which was eight yards south

Digitized by Google

from the house, and facing it, and saw the house blown away. It was struck from the southwest. First, a portion of the roof was blown off, then the house went bodily like lightning. When the house had gone I came out of the cave and was blown to the east-southeast.

Sketch of Mr. Waters's house.

Mr. Waters's house was 30 by 16 by 11 feet without the roof. It was carried, sill and all, twenty-four yards down a declivity without being turned round or tilted over. When it struck the ground, it at first merely shaved it with the foremost sill, gradually going deeper until the resistance became so great as to cause the house to turn over, when it went to pieces. The ground was plowed up about two feet at the deepest point. The house had fallen three feet in traveling twenty-four yards. Its weight was at least ten tons.

Between the cave, which was only about four feet above the surface, and the house, but nearer the cave, stood a small tree. Against it a spade was leaning. Mr. Waters testified that it was not blown down. Two yards east of the tree stood a bucket containing a small quantity of lime, and weighing ten pounds. It was not disturbed. To the southwest of the cave the trees were comparatively uninjured over a triangular space, while on either side they exhibited signs of the greatest violence. An oak rail, which had evidently been carried with the house until it struck, and then hurled due east, was driven four feet into the soil at an angle of 45°. Its dimensions are 16 feet by 8 inches by 8 inches, and its estimated weight three hundred pounds. It was found eighteen yards east of where the house struck.

Mrs. Waters was carried with the house until it went to pieces, and received injuries of which she died. The fragments of the house were carried far in the line of the storm.

Alexander Gibson had two houses, both situated as nearly as possible in the center of the storm. The first house struck was taken away without touching the ground and went to pieces in the air. The other house, in which were seven persons, was swung round on its northwest corner, as on a pivot, the south end traveling 36 feet and cutting up the ground as it went. It then turned over and was demolished. During this journey the floor was broken up and three persons fell into the cellar. The house was a large one. It afforded no good basis for calculation on account of the irregularity of its shape. A granary was pushed due east 14 feet. Its dimensions are 16 by 16 by [illegible] feet. It is strongly built of generally hard wood, and divided into compartments. It was full of grain. The weight of the building and grain was given at 60,000 pounds. The resistance to its forward motion was very great, because it was surrounded with wet straw and rubbish, of which it had pushed quite a pile before it. It was racked by the strain which had been put upon it. Missiles had been driven through three hardwood planks, in succession, of an inch thick. They consisted of small pieces of wood, but had been removed. A plank 16 feet long, 2 inches thick and 1 foot wide, was driven 4 feet into the soil, at an angle of 45°. A corn-sheller, weighing six hundred and forty pounds, was carried four hundred yards and destroyed. Trees were barked

Digitized by Google

but without any symptoms of electric action or of explosion. The general position of trees and ruins was entirely corroborative of what has been already proved by an overwhelming mass of evidence, viz, the rotation and direction of rotation of the storm.

J. K. Marbourg, Jackson Township, section 17, witness: (House eighty yards from storm-center, with an excellent view of Gibson's house.) Watched the storm a long time before it came. The west was first filled with clouds which extended until they covered all the western and northern heavens reaching a little beyond the zenith. The tornado first appeared as two clouds, one from the southwest and the other from the west rushing to one point. Together they presented somewhat the appearance of an arrow, thus—

The whirl was seen forming when they met. Above them were dark, heavy clouds When the tornado came nearer it presented the appearance of one funnel, revolving contrary to the hands of a watch, and drawing everything up, thus—

When at Gibson's house, where I had the best view of it, and where it was one hundred nd twenty rods distant, it presented the appearance of two funnels uniting in one, at e height of 40 or 50 feet. The bases of the two funnels were about 200 feet apart. ney presented somewhat like the following appearance. The two funnels did not pear to revolve around each other. The first came to the east of Gibson's house, took s stable, and then turned back to his house. The two then appeared to unite. Could

see the two afterward. The tornado disappeared behind a building. It grew y dark. The funnels were of a dark blue. Everything in them was rising. The

Digitized by Google

timbers from Gibson's house flew up. Did not see clear sky through the open space between the two funnels, but a bright yellowish hue. The upper funnel extended to the clouds above. Hail, or rather chunks of ice, from a pigeon's to a hen's egg in size, fell before the tornado column came in sight. The wind then blew gently from the east. After the tornado had destroyed the school-house, there came a violent gust of wind from the northwest, which considerably damaged my out-buildings. I had started to go to the school-house, and it carried me several yards before it. Immediately there fell a torrent of rain, with cold wind from the north. Was near where the school had been, but could not see anything. Suddenly saw the teacher and children, as if they had sprung out of the earth. They were coming toward me. They were shivering. They could give no account of what had befallen them. Never saw such miserable-looking beings in my life. I had four children there, and did not recognize them. The mud was pelted into their skins, so that it could not be washed out. It is not all washed out yet. A dead child was found forty yards northwest of the school-house. The storm opposite my house was a mile wide. An oak-post 4 inches in diameter was perforated by an oak-board 4½ feet by 4 inches by 1 inch. (It had been thrown among the other rubbish and was not to be found.)

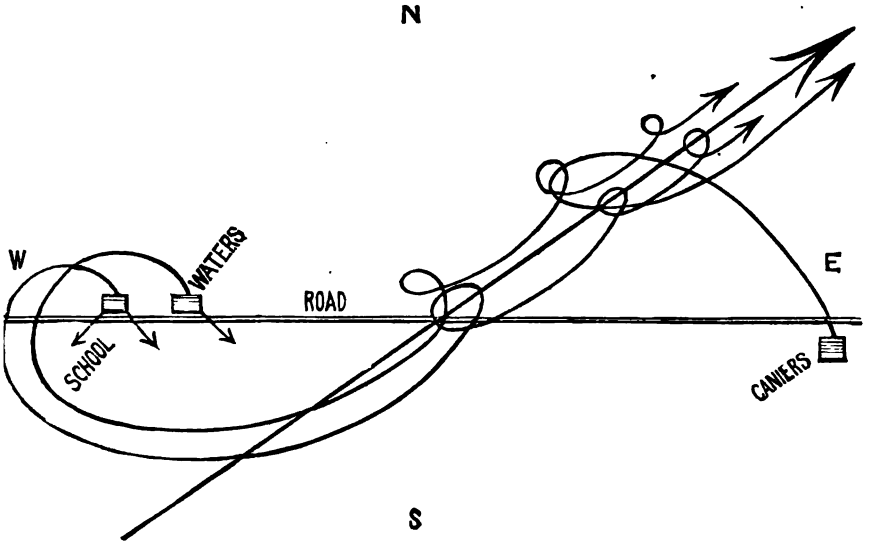
James Clancey, residing with J. K. Marbourg, testified that he viewed the tornado from the same position as Mr. Marbourg and saw only one funnel. I do not, however, estimate his observing powers so highly as those of his employer.

David Canier, Jackson Township, section 20, witness: Watched the funnel as it approached. It was perfectly dark in it. Could see boards flying out at the top of it. It was very large at the top and small at the bottom. It grew dark as night. Six persons took refuge in the cellar. The house went immediately like the clap of a hand, and the darkness was already gone. Then it turned pretty dark again, and rain fell in a sheet. It did not fall in drops. It was all over in a minute. Things in the cellar were not much disturbed. Bottles stood where they were.

Alexander Gibson, witness: Was at Mr. Canier's house. Hail as large as pigeons' eggs fell about twenty minutes before. Heard the noise about half an hour previous to the storm. Saw clouds coming from the north and south, and rushing together. Saw the funnel when three miles distant. Watched it when thirty or forty rods distant. It was then as black as night, with boards flying around it. A very strong wind was blowing. It grew dark as midnight. Rushed down into the cellar, and was barely down when the house was struck with a sharp, instantaneous rap, and in a moment it was gone. It was dark when I went down into the cellar. It was pretty clear as soon as the house went. It then grew darker again, and a tremendous rain came down. Saw no lightning. Heard no thunder. On my farm a beam was driven right through a hog.

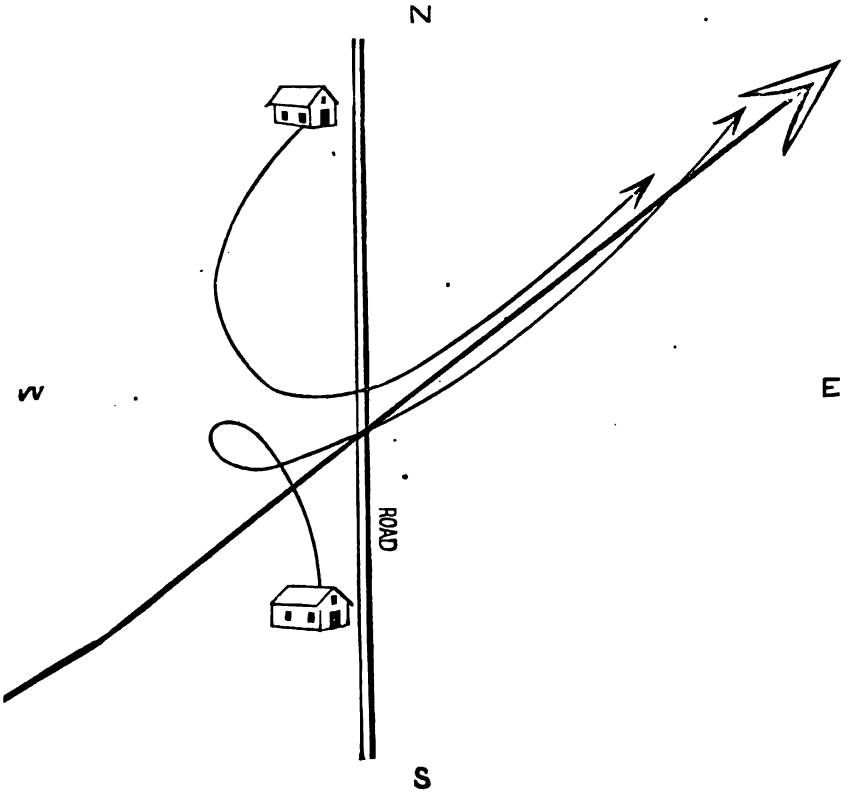
Mr. Canier's house was 24 by 28, by 14 feet to the eaves. It was pushed 18 feet due north without touching the ground. Its edge then came in contact with the soil and with tree-roots, having fallen two feet from its original position, and the house toppled over, and was blown to fragments. The ruins were carried first to the northwest and then around to the northeast. Heavy oak-sills were carried hundreds of yards and broken. The strongest iron-bound machinery was knocked to pieces, and carried away. The sickle-bar of a Buckeye machine was carried thirty rods. A beam 14 feet by 6 by 6½ inches was driven 3 feet into the soil in a slanting position. The beam weighed about fifty pounds.

A half mile to the west of Mr. Canier's house stood the school-house already mentioned and a house occupied by Henry Waters. Between these buildings and Canier's house, and about one hundred yards to the northwest of the latter, passed the storm-center. The house occupied by Mr. Waters and the school-house were first blown to the northwest, and then in a circle by the south around to the northeast. A heifer ran along the road which connects the houses. It presented the appearances already described.



The house occupied by Mr. Waters was first blown to the northwest, the sills remaining. The sills were afterward blown to the southeast. The sills of the school-house had likewise, after being deserted by the house, been pushed to the southwest, and finally the position of the *débris* among the ruins showed there had followed a violent wind from the northwest; thus a tree lay across the foundation of the school from the northwest.

L. B. Babcock, son of J. P. Babcock, Jackson Township, section 17, witness: Hail fell before the storm as large as pigeons' eggs. Ran to get into the cellar. Cellar-door was blown over me as the house went. Came out of the cellar immediately, and was blown south. The rain then came down in sheets, with a north wind. The shutters from the house were carried three or four miles at least. Jacob Zeck got only partly down the cellar-stair and was hurt in the head.



J. P. Babcock's house was 34 by 26 by 14 feet to the eaves. The gable-end faced the wind. The house was pushed bodily toward the north, crushing the northern foundation; tore up the ground a short distance, toppled over, and went to pieces. It stood on the southeast of the storm-center.

Digitized by Google

Jacob Zeck, Jackson Township, section 17, witness: Was going down Babcock's cellar-stairs when his house flew away, and injured my head severely.

Representation of effects of the storm at these houses.

Sketch of the effects of the storm at Babcock's and Zeck's.

Digitized by Google

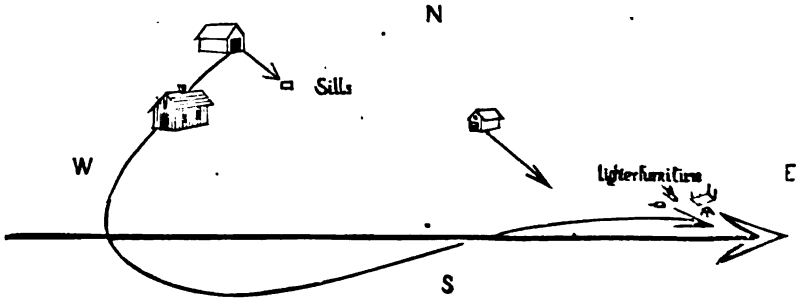
Mr. Zeck's house stands on the northwest edge of the storm. It was pushed from its foundations 12 feet to the south-southwest, plowing up the ground. The windows on the north side were smashed in. The windows on the south and east were blown out. A hay-stack was entirely blown away. It went, as could easily be traced, first south-southwest, and then round in a circle to the northeast. It went forty rods south before turning east.

The distance between these two houses was about half a mile. At this point the storm-path turned a little nearer north than northeast.

J. H. Laughhead, Jackson Township, section 16, witness: A little hail fell before the storm. It rained awfully for half an hour after it. Wind, during the rain, was from the northwest. It was very dark. Saw no lightning.

The house of this witness stands on the northwest side of the storm-center, about one-third of a mile distant from it. The fences were blown the usual way.

Levi Moothart, Cedar Township, about two miles north of the path of storm, witness: There fell the heaviest rain I ever saw; also hail as large as hens' eggs. The rain lasted about an hour, and the whole country was under water. The wind, during the rain-storm, changed from south to west and north, and at times it was very strong.



F. M. Curry, Jackson Township, section 9, tenant of John Flack's house, witness: The family went to the cellar. The house went south. No one injured. Eighteen panes blown away.

The house was pushed 45 feet due south and then went to pieces. No explosion. It was situated to the northwest of the center.

E. N. Wright, Jackson Township, section 10, witness: Was on the southeast side of the storm. Saw distinctly, at the distance of two miles, the tornado in funnel-shape. The small end was down. Saw wood whirling. Heard its roaring after it went east. There appeared to be a mist or steam in front of it. It rose and fell. A few hailstones fell before the tornado and an exceedingly violent rain after it.

Mr. Wright's house stands on the northwest of the center of the storm-path, about fifty yards from it. A wood-house and kitchen were blown southwest. The dwelling-house, a large, strong structure, was moved one inch to the east. A stove weighing four hundred and fifty pounds, and exposing to the wind a surface of 3 feet by 21 inches, was pushed 12 feet to the southwest, where it was stopped by obstructions. A bell, weighing one hundred and fifteen pounds, not under any circumstances exposing a greater surface than one square foot to the wind, and mounted 12 feet high, was broken from its fastenings and carried 60 feet south. A granary, measuring 28 by 16 by 12 feet, and weighing, together with the grain, fifty-five thousand pounds, was carried twenty-one yards to the southeast. After plowing up the ground 2 feet in depth it tumbled over and went to pieces. It was carried down a declivity, falling 6 feet. The width of the storm-track here was half a mile.

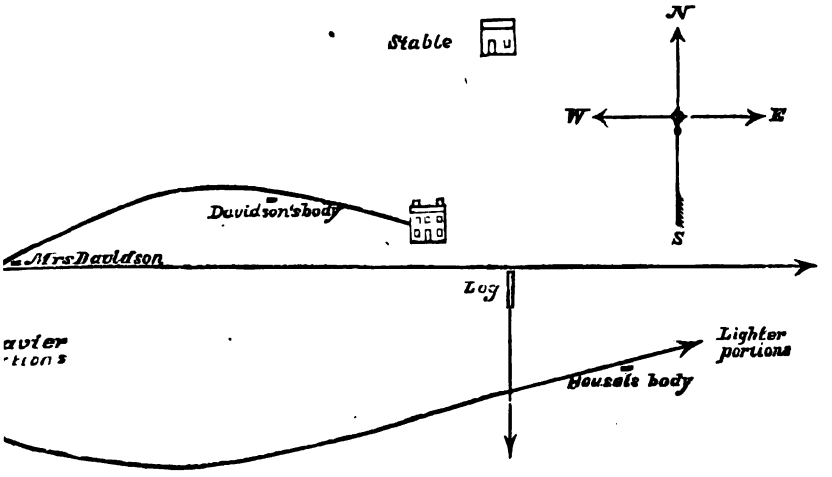
J. T. Anderson, tenant of J. C. Cunningham, witness: Was at Grand Prairie U. P. church, three-quarters of a mile northwest of storm-center. The wind blew so strong as to endanger the building.

Plan of ruins of Cunningham's house.

J. C. Cunningham, Jackson Township, section 11: The house of Mr. Cunningham stood on the northwest of the center of the storm-track, yet within the most violent vortex. The house was blown to the southwest; but the east door having been blown in, the house went to pieces without tumbling over, and the floor remained upon the ground. The lighter furniture, &c., was carried far to the east. The granary stood to the northeast of the house. Its contents were emptied into the house-cellar. The wheat the granary had remained when it was carried away. They were afterward found to the southeast. A barn was blown to the southeast. A hog, weighing two hundred pounds, was carried five hundred yards. A cow, weighing one thousand pounds, was carried two hundred yards.

Digitized by Google

There were four persons in the house and none were killed. The path of the storm here five hundred yards wide and nearly due east.



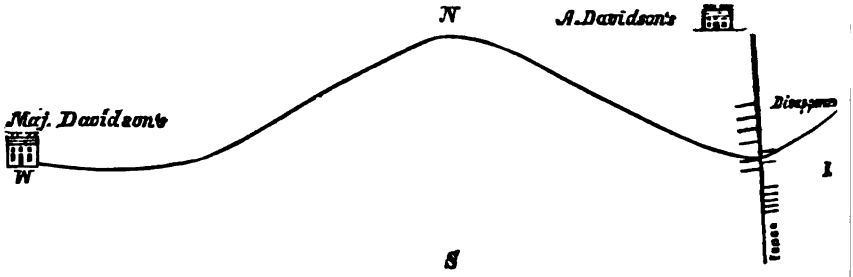
D. T. Carringer, Jackson Township, section 15: The house stood on the south edge the storm. It was carried to the northeast 17 feet, going deeper into the soil as it nt. It then turned over and was blown away in fragments. The straw among the es showed that the last gust came from the northwest.

Josiah Condit, Jackson Township, section 11, witness: No hail fell before the tor-do. It rained terribly right after it. The wind was blowing from northwest as the in fell. Saw no lightning.

Mr. Condit's house stands upon the southeast edge of the storm, which here traveled arly due northeast. There seems to have been a streak of exceptionally strong north-st wind, which struck the barn and corn-crib, and cut its way through the gar-n fences. The center passed along the fields, producing upon fences and hedges the ne effects as those already described.

The next house struck was that of J. M. Davidson, Highland Township, section 7: stood precisely in the storm-center, which here, as if conscious that this was its last tim in Iowa, seems to have exhausted its utmost violence. The house, 18 by 12 by feet, was blown bodily from its foundations down a declivity toward a slough. It er touched the ground, but was shattered in the air. It seems to have been carried t nearly due west, and then the lighter portions round in a curve to the east. The ly of Mr. Davidson was found twenty yards west of where the house stood. The ld was blown still further in the same direction. Mrs. Davidson was carried about hundred yards west. The body of Leyden Housel was found to the southeast. The vier portions of the house were found some hundreds of yards to the west. Mr. usel's body had evidently been carried west with the fragments of the house and n back to the east. Mrs. Davidson and the child escaped with their lives.

log of green water-elm, 7 feet in circumference, 8 feet in length, and weighing east a ton, was carried fifty yards straight south. A horse, weighing one thou-d and eighty pounds, was carried forty-five yards. A hog, weighing three hundred nds, was blown thirty yards. The stable and barn were blown south. An iron v, with wooden handles, was carried one hundred and fifty yards. The strongest -bound machinery was utterly destroyed. The young trees in the orchard were er barked or torn out. The storm was exceedingly violent for a breadth of one dred and fifty yards, but fences were blown down for nearly a mile wide. At the se of Thomas Davidson, a quarter of a mile to the north, the wind blew so strongly : the door had to be held. The north wind was evidently subsequent to the east d, because the house could not have stood such a wind.



Plan of the ruins of J. M. Davidson's house.

Davidson, Highland Township, section 7, witness: It commenced to rain about ten enty minutes before the arrival of the tornado. Shingles and other stuff began to vith the rain. Then went out to see where they came from. Saw the tornado t thirty rods distant. It appeared to be coming toward me. Saw it bend to the east. It was funnel-shaped and as black as possible. It whirled. Thought it led with the hands of a watch. It passed twenty rods to the south of the house

Digitized by Google

and bent again to the northeast. When thirty rods distant from the house it sud- disappeared. Afterward saw another funnel, not reaching to the ground, tra toward the northeast. When first seen it appeared to be only 60 feet above the gr at its lower end. The farther it went the higher it seemed to get.

Mr. A. Davidson's house is situated one-half a mile east of where J. M. David house stood, and a little north. The shingles and other material he saw falling from his brother's house. The following sketch shows the direction of the storm after leaving Major Davidson's place until it ceased to touch the earth as a fu

Twenty rods south of A. Davidson's house it crossed a fence, exhibiting the sam pearances as those already described. I was particularly careful upon this point, be of Mr. Davidson's belief that the funnel whirled with the sun. I thought it pr that the tornado, before lifting from off the ground, might have changed its direc rotation. But the evidence to the contrary was so striking that Mr. Davidson a upon my pointing it out to him, admitted that he must have been mistaken. He ha paid particular attention to the matter, and it was very dark when his observa were being made. The fence in question ran north and south. It was only thr down for a space of sixty yards, and the boards were not carried away except i middle. The posts remained in the ground, those on the north of the center lea west and those on the south leaning east. The posts in the center were leaning one way, some another. The funnel disappeared upon a knoll in the midst of a about one-half of a mile in diameter. There was no *débris* deposited at this poin were there any signs of a cataract of water having poured down. The wheat, ho ever, was mown as low as possible, and the ground looked as if it had been baked cording to Mr. Davidson's statement. The funnel had narrowed to a point bef disappeared.

After leaving Mr. Davidson's the tornado-cloud traveled to the southeast. Its pr ress was now difficult to trace, because of the little attention usually paid to a cloud, a high wind, and a rain-storm. Considerable time had also now elapsed the meteor passed.

James M. Mace, Highland Township, section 8, had several panels of fence b down by a westerly wind. A few small hail fell before the wind and a very he rain after it.

J. W. Haskett, Highland Township, section 9, witness: Six or eight panels of fenc my farm were blown to the southeast. A few hail and some rain fell. The wind from the northwest when raining. Saw some lightning. Heard roaring about half an hour before it came. Saw funnel strike the ground. Saw it rise at Davids Saw it strike the ground afterward. The wind blew very hard.

This witness's house is two miles from Davidson's.

William Dennis, Highland Township, section 10, witness: A few panels of fe blown down to the east. Small pieces of boards, shingles, and laths were dropped hailed a little before and rained a good deal after. The wind during the rain was the northwest.

John W. Guthrie, Highland Township, section 11, witness: A few panels of fe were thrown down to the east.

George Wallace, Highland Township, section 11, witness: Heard roaring. It grew very dark. A high wind about one-half mile to the south of witness.

J. H. Lyttle, Highland Township, section 12, witness: Had nearly half a mile fence thrown down. The east and west fences were blown south; the north and so fences east. Heard roaring an hour before the storm came. The roaring was mo before it came than after it was here. Did not hear it after it passed. Saw the c until it came within three miles' distance. The whole northern portion of the sky covered. Saw a cloud rushing from the south and another rushing to meet it fro north. The clouds rushing north appeared to be the lowest. After the cloud overhead could see the lowest clouds rushing rapidly from the south. The broken clouds. Through them could see a higher current rushing from the north

Digitized by Google

ittle hail and rain fell. The wind changed from the south to the west and northwest s the storm passed. The width of fence blown down was about one hundred and fifty ards.

Michael McGuire, Highland Township, section 12: One-half mile of fence on the arm was blown down. The chimney was blown off and some trees leveled. All was lone by a northwest wind. It hailed a little and rained very heavily.

The storm now passed out of Washington County into Louisa County, traveling outheast.

Joshua Luckey, Louisa County, Union Township, section 17, witness: The path of ences blown down on my farm was about six hundred yards wide. The fences on the vest of the center were thrown north; those on the east were thrown south. A few ail fell and a smart shower of rain. Heard no roaring after it passed.

Charles Crim, Union Township, section 20, witness: Fences, two hundred yards ide, thrown down to the southeast. The roaring was very loud for an hour previous o its arrival. Did not hear it after it passed. Saw no lightning. Saw a tongue of oud shaped like a funnel hanging from the clouds. It did not reach the earth. At rst it was hanging perpendicular. Then it commenced whirling like the tail of a spended snake.

At this point I lost track of the tornado and could not recover it, although I spared either time nor pains. Only now and again could one find a man who could give ny information even of what happened on their neighbors' farms a week or two before.

John Colton, Columbus Junction, witness: There was some hail, a brisk wind, and tremendous rain.

Mrs. Snyder, Oakland Township, section 9: Heard roaring distinctly. There fell a ry heavy rain, which continued until nearly dark.

Peter Attig, Johnson County, Tremont Township, section 22, witness: About 4 p. m. ere was a terrific rain-storm, with hail as large as hickory-nuts, and accompanied th thunder and lightning. My barn was struck by lightning. Perkins's barn was so struck.

Lone Tree Station: About 4 p. m. there was a violent storm of rain, hail, thunder, d lightning.

Nichols Station: There was here a high wind, with heavy rain and hail, and accompanied with thunder and lightning.

At this point I gave up the search and took train for Illinois. Previous to describing effects there, the following testimony may find a place:

H. C. Vittitoe, Warren Township, Keokuk County, about three miles northwest of e tornado, witness: Saw a little south of the zenith the white under-clouds rushing circles to a center. The gyration was contrary to the hands of a watch. The funnel d not yet touched the earth. The wind came from the northwest pretty strong after passage of the tornado, bringing with it a little rain and hail.

Dr. W. D. Hoffman, Sigourney, witness: Mrs. A. T. Page collected a number of the gest hailstones. When melted it was found that they had contained a quantity of igs, leaves, dry grass, and mud, all reduced to fine proportions. Hail weighing from r to eight ounces were common. One hailstone which was shaped like an apple, measd 4½ inches in diameter. The roaring was heard about twenty minutes before the l began. It rose and fell like the cannonading in a battle. During the hail the nd came from the northeast, but it was very light. Sigourney is four miles north the storm.

saac Farley, Foote Town, Iowa County, twelve miles north of Keota, witness: ere was very little rain and no hail, but the sound was loud and distinct.

. R. Eldridge, Washington, Iowa, witness: Watched the tornado from the roof of ouse. Did not see a funnel appearance. The roaring was very loud and the cloud y black. The cloud appeared to bend forward. The elevation of its summit was ut 35°. The distance five miles. Its summit was completely hidden by an overging cloud, which extended south a little beyond the zenith.

rthur Howell, who was at Yalton, Iowa Township, five miles north of the tornado, ified that hail larger than hens' eggs fell, and a terrific rain of an hour's duration, ompanied by incessant thunder and lightning.

xtracts from a communication received from R. L. Jay, Harper, Keokuk County, sician:

Was in the village of Baden, Keokuk County, German Township, three miles to northwest of the storm-path.

The tornado maintained an upright position. It moved rapidly at times, at others ning to remain quite still. It was apparently about a quarter of a mile in height, was funnel-shaped and very dark and angry-looking. It whirled with the hands watch. There was a continual whirling of the clouds above the funnel. This observed for some time after the storm had passed. Saw no lightning and heard hunder. It was impossible to hear thunder owing to the noise of the storm, which terrific. The direction of the wind was northeast until the storm had passed, en it changed to the northwest. Rain fell in torrents. Quite an amount of hail of all conceivable shapes. Three were picked up weighing one-half of a pound a. Half an hour after the storm the thermometer stood at 92°."

Digitized by Google

G. W. Brockway, Talleyrand, witness: No rain nor hail fell here. A heavy ra[in] about one mile to the north. The edge of the cloud did not reach the zenith by a[bout] degrees.

Extract from the Sigourney News, May 28, 1873:

"While the cyclone was mowing its path a few miles south and east of Sigour[ney] tremendous hailstorm visited this locality. We saw one hailstone which w[eighed] eight and one-half ounces. The hailstorm was followed by a heavy rain, after [which] the sun came out bright and pleasant for the rest of the day."

Extract from the Washington County Press of May 28, 1873:

"The writer was in a street-car, half way from Moline to Rock Island, at 4.3[0] p. [m.] on Thursday, when it was struck dead ahead by the most terrific wind and rain-[storm] we ever experienced."

S. J. Mather, editor Wilton Chronicle, Iowa, witness: Between 4 p. m. and 6 p. m. a very dark cloud passed over, which poured down a very heavy rain.

Extract from the Chicago Tribune, May 25, 1873:

"At Muscatine the rain came down as if the flood-gates of heaven had been op[ened] followed by hail. Between there and Wilton Junction, at Monona, Fredonia, [and] other stations along the southwestern division of the Chicago, Rock Island and P[acific] Railroad, the country was flooded."

The tow-boat Victory lost her pilot-house and smoke-stack when near Buff[alo] the Mississippi. The tug Nonesuch lost her smoke-stack and pilot-house at M[uscatine]. She was driven ashore.

A. H. Swan, editor of the Monmouth Review, witness: There was an exceed[ingly] heavy rain, a little hail, and a great deal of lightning about 5 p. m. The atmos[phere] smelt as of brimstone previously. It was oppressively hot; perhaps 95°.

The temperature and pressure on May 22, 1873, at places near the tornado:

	Davenport.		Keokuk.		West U[nion]
	Bar.	Ther.	Bar.	Ther.	Bar.
7 a. m	29.73	64	29.64	69	29.[6]9
2 p. m	29.60	77	29.51	85	29.[4]
9 p. m	29.69	66	29.71	72	29.[5]

The condition of the barometer and thermometer at West Union was obtained [by] Frank McClintock, correspondent of the Smithsonian Institution, who also furnish[ed] following noteworthy fact: "Wind changed from the south to the west rap[idly] 3.45 p. m. It worked back to the south before 9 p. m." The relative humidity [was]:

	Davenport.	Keo[kuk]
7 a. m	94	[ ]
2 p. m	77	[ ]
9 p. m	94	[ ]

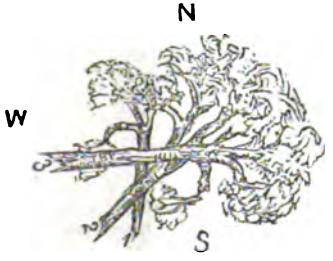
We do not, therefore, overrate the relative humidity when we estimate it at [80] cent. at 2 p. m. The average temperature at the earth's surface in the line [of] tornado at 2 p. m. was, from the above, probably 76°, but in the wooded hollows [it] greater.

Mr. Jay, however, of Harper, Keokuk County, states that the temperature [was] half an hour after the storm. The day was generally described as being very [hot].

Having arrived at Prairie City, Ill., I endeavored to find out the exact locality [at] the tornado first began to overthrow fences, damage buildings, &c. On the far[m] James Williams, Point Pleasant Township, Warren County, there was a strong [wind] but not sufficiently so to prostrate fences. About one mile to the east is the fa[rm] Israel Jared, Point Pleasant Township, section 24. Mr. Jared testified as [follows]: Saw streaks of cloud moving from the north and south toward each other before [any] thing touched the earth. Saw a cloud in the form and about the size of a ha[y]-[stack] strike the ground on my farm. A few minutes before, hail of moderate size [and] small quantity fell, followed, as the whirlwind was passing, by a smart shower of [rain]. The wind, which had been southeast, changed to the west after the tornado [passed]. It was pretty warm before, and cool after it. Heard roaring some five minutes [pre]vious to the arrival of the storm. Fences were blown down for two hundred yards [to] They were blown toward the east. Saw some lightning. There was a heavy cloud [in] the north as the storm approached.

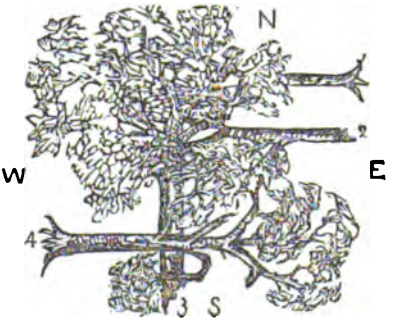
Mr. Jared's house stands about two hundred yards north of the storm-path. [The] tornado was here traveling a little to the north of east.

John F. Tatman, Israel Jared's farm, testified that he saw the funnel strike the [farm] and that he heard the roaring for a long time previous.



Before leaving this farm the storm had developed all the characteristics of a tor[nado] except that the east wind was not yet powerful enough to destroy. The whirl[wind] then passed along a ravine full of tall timber. Nearly all the trees were uproot[ed] broken, but generally the latter. They appear to have had a firmer hold of th[e]

Digitized by Google



than those in Iowa. The breaking usually occurred about six feet from the ground and the barking was almost entirely confined to the broken trees. The bark was torn off both up and down from the place where the timber was broken. The trees, when sound, were seldom broken clean across. Half or more of the wood was severed, and the remainder was bent so as to allow the tree to rest upon the ground. The broken timber, when sound, invariably presented the appearance of a broom. The fibers of each year's growth were loosened from the others and split. It was easy to obtain pieces ten feet long and as thin as a wand. This separation of the fibers had evidently been brought about by the excessive straining and bending of the tree before it fell. Each year's growth had apparently been snapped asunder by itself, beginning at the outside. The trees all lay as they had fallen, being, when once down, protected by the surrounding timber. If they had, after falling, been subjected to a wind from another direction, so as to break them off entirely, they would have presented the precise appearances which have, by certain meteorologists, been attributed to the action of electricity. Many of these broken trees were two feet in diameter. When a tree, still standing, had its bark torn off at any point, an examination generally showed that the fibers of the tree were separated and perhaps partly severed at that point.

No. 1 lay beneath, diameter 8 inches; No. 2 lay above No. 1, diameter 26 inches; No. 3 lay above No. 2, diameter 26 inches. As the tornado increased in power the position of the overthrown trees varied more and more from a westerly direction; some weak ones lying from the south-southeast south of the center.

The following is a sketch of trees found in the center, one-quarter of a mile farther east than the above:

Sketch of fallen trees.

Nos. 1 and 2 lay beneath, diameter 6 inches; No. 3 lay above Nos. 1 and 2, diameter 18 inches; No. 4 lay above No. 3, diameter 15 inches.

Mason G. Buck, village of Swan Creek, witness: Saw a distinct funnel-shaped form. It appeared to jump up and down 50 feet at a time. It hailed a little before the storm and rained a little after it. Heard a roaring about twenty-five minutes before it arrived. Saw no lightning. Saw only one funnel. Trees were blown down in my yard from the northwest. My house is a half mile south of the center.

Leroy Putnam, near Swan Creek Station, witness: It looked like a top and whirled contrary to the hands of a watch. Saw it rising and falling. My house is about half a mile south of the center. It blew very strongly here. The tornado at this point was traveling east-northeast.

William Huston, Swan Township:

Mr. Huston's house stands on the north edge of the storm-path. The roof of the barn was blown to the southeast. A corn-stump about two inches in length was driven through the bark of a large tree, leaving its impress upon the wood.

John Worden's unoccupied house, one-quarter of a mile east of Huston's, was completely demolished. It stood near the center. The orchard was uprooted. Trees which had stood one hundred and twenty yards southwest of the building lay with their branches upon the foundations. The larger timbers of the house lay a few yards to the west and north. The lighter were blown away. The breadth of desolation was here one hundred and fifty yards. At this place the tornado seems to have made one of its sudden dips, the trees on the west and south being uninjured.

Shortly after leaving Worden's house the tornado entered the timber on the north bank of Swan Creek. It increased greatly in power and width as it did so. So long as it followed Swan Creek, fences were thrown down over a space of from one to one and a half miles wide.

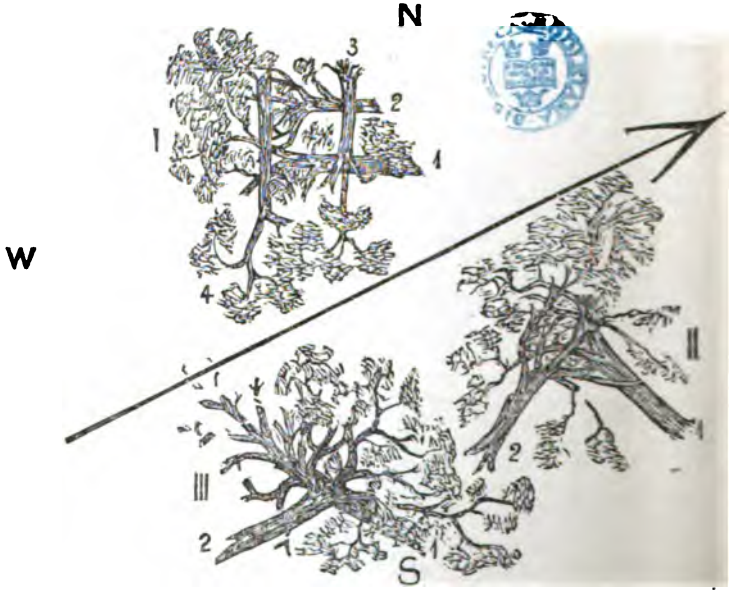
Franklin Booth, Swan Township, section 18, witness: Hailed just before the storm as large as hazel-nuts, with a northeast wind. It did not rain much. Saw lightning toward the south. Mr. Booth's house stands on the north edge of the storm.

Digitized by Google

Abraham Stanfield, Swan Township, section 18: The storm-center is one-quarter of a mile south-southeast of Mr. Stanfield's house. The fences were generally thrown south. Among Mr. Stanfield's timber, near the creek, the storm wrought complete ruin. Three typical groups of fallen trees may be selected. Group I, a little north of center: Nos. 1 and 2 were blown down from the east and lay below Nos. 3 and 4. They were between one and two feet in diameter. Group II, a little south of center, and seventy-five yards distant from Group I: No. 1, blown down from the southeast, lay over No. 2, blown down from the southwest. No. 1 was 15, and No. 2, 10 inches in diameter.

Group I.

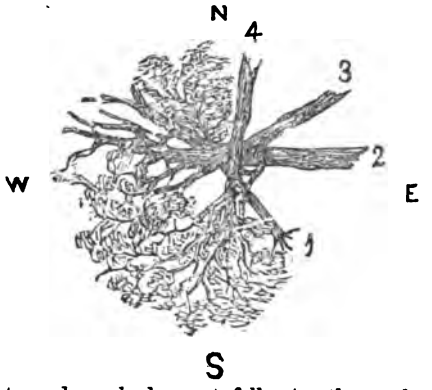
Group III, a little further south of center than Group II, and near it: No. 1, a decayed tree 16 inches in diameter, lay under No. 2, 14 inches in diameter.



Group III.

Group II.

The storm at this point overthrew all trees of any dimensions for a width of two hundred and



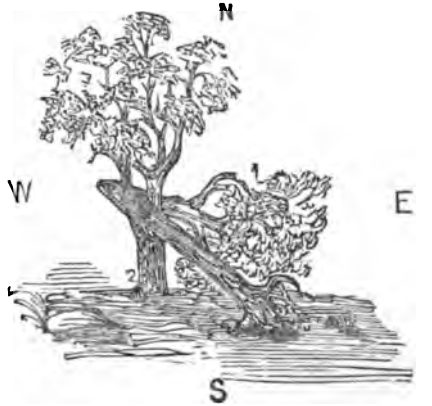
The three groups combined.

yards. The following group of trees was found about one-half a mile further on. It was just within the most violent vortex of fifty yards in width, and a little to the north of the center. The trees lay as they fell: No. 1, 12 inches in diameter, from the southeast; No. 2, 13 inches in diameter, from the east; No. 3, 14 inches in diameter, from the northeast; No. 4, 16 inches in diameter, from the north. No. 1 was lowest, No. 2 next, No. 3 next, and above all lay No. 4.

The path of the tornado was here exceedingly well marked among the timber trees. It could be followed by the eye as far as the ground permitted. The

Digitized by Google

torn and bare, while all around was green. This barking of the young trees took place within much narrower limits than those within which grown timber was overthrown. Generally they did not extend over twenty to thirty yards in width, and were sometimes much less, and even disappeared altogether. The trees exhibited the marks of the greatest violence on the side from which the storm came. The twigs were smashed and broken off, the bark partially removed, and even the timber bruised. These results were evidently the effect of a rush of missiles against the trees.



The tornado at one point suddenly narrowed the path of extreme violence from fifty yards to twelve yards, at the same time changing its course to the southeast. This change of direction brought it toward Swan Creek, along the northern bank of which it had hitherto been raging. Just as it struck the creek the track was nearly south-southeast. Immediately thereafter it turned nearly due east, following the creek. The bottom of the ravine within which Swan Creek flows is about two hundred yards wide, is surrounded by steep and lofty bluffs, and was covered with large trees. Among these trees the whirlwind raved with the utmost fury, developing an energy surpassed at no other point in its career. Trees from three to four feet in diameter were snapped or uprooted. Many large trees were broken off at a height of about 40 feet and left without a twig. By far the greater number of trees along the ravine were thrown down from the southwest. The same broom-like appearance was generally presented by the broken trees as already mentioned.

Thomas Warmoth's house stood in the bottom of the ravine. Mrs. Warmoth testified as follows: Heard a roaring first. When the storm came near the roaring was louder than thunder. A few hail fell just before the tornado blew. It was immediately preceded by a very bright flash of lightning. Went into the house and got upon my feather-bed, together with my child, because I was afraid of the lightning. A large tree was blown down catching the side of the house. The house went to pieces, the tree, however, keeping the floor in its place. Found myself under the feather-bed with my child. The bed was pinned to the earth by pieces of timber. Was soaking wet. Everything was covered with mud. Heard no thunder. The lightning struck the tree, depriving it of its bark.

I was unable to find this tree. Mrs. Warmoth's testimony is valuable as a curiosity. It was generally impossible to obtain any information from the ladies. If one questioned them rigorously they took it as an insult, and if allowed to tell their own story they immediately commenced running such a muck among the prodigious and the indelible that one was glad to make his escape. In this connection it is also worth mentioning that although invariably offering payment for any necessary hospitalities, I soon learned the wisdom of always addressing myself to the master of the house when asking for such.

No. 1 is a tree 18 inches in diameter. No. 2 is a tree 2 feet 6 inches in diameter, but broken at the height of 15 feet from the ground. No. 1 was blown from the south-east between the forks of No. 2 and then half broken close to the forks and blown from the northwest until its top nearly reached its root.

Group of trees near Warmoth's house.

After leaving Warmoth's house the tornado-center crossed to the south bank of Swan creek, where it continued for nearly a mile farther, although somewhat increasing its distance from the creek. It crossed to the south bank, where a smaller creek joins Swan Creek from the south. This brought it nearer to the house of A. J. Caton, Swan township, section 15, which stands about three hundred yards from the center of the whirlwind. Part of the roof was blown to the southeast and part to the northeast. A smaller house was blown a few yards to the southeast and inverted. A house on Mr. Caton's farm, tenanted by N. J. Reynolds, 14 by 20 feet and one story high, was carried

Digitized by Google

eight yards to the northeast bodily. It then struck the ground, tumbled over, and was blown to fragments. Its four inmates were carried from fifty to sixty yards, but were killed. It stood a little south of the center. After passing Mr. Caton's farm the tornado entirely left Swan Creek. Before tracing its further progress, it will be best to give the evidence of people living at or near Youngstown, about one mile south of the center:

Charles McCormick, Swan Township, witness: The tornado looked as large as a house when three miles distant. A little rain and hail fell. The wind with the rain was from the west. There was no wind to do any damage. House a quarter of a mile south of Swan Creek. Time, about 5.45 p. m.

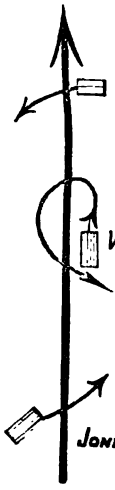
H. W. Simmons, Swan Township, section 28, witness: The time when the tornado passed was about 5.40 p. m. Have good grounds for this assertion. A few minutes before its arrival I noticed a very black cloud in the west with a lighter space on each side of it. My house is three-quarters of a mile from Swan Creek. Did not hear the roaring very distinctly until it was nearly opposite. Then it was an awful terrific roaring. Then it presented the appearance of a funnel apparently only a few rods across at the bottom. The top of it appeared to be from three to four times wider than the bottom. Did not notice whether it entered an overhanging mass of cloud. Was hailed a little when it was opposite. Fences were blown down fully a mile and a half to the south of Swan Creek.

H. A. Folger, M. D., Youngstown, one mile south of Swan Creek: The tornado was opposite about 5.45 p. m. Saw dark clouds in the west-northwest for an hour previous. There were several bright flashes of lightning after the tornado. A few hailstones as large as bullets fell as the tornado was passing. It rained very hard for a few minutes after. It was quite dark for a little time. Saw clouds rolling and tumbling. The strongest gust came from the west-northwest.

In Youngstown a few chimneys were blown off and similar damage done. One house was moved from its foundations to the northeast. Trees, in a few cases, were blown down, and all to the east. It is to be noted that, while at McCormick's house, a quarter of a mile south of Swan Creek, along which the tornado passed, no damage was done by the wind, at Youngstown, three-quarters of a mile further away, the gale was almost strong enough to blow down houses. McCormick's house is somewhat blown down and stands among trees.

After leaving Swan Creek the storm traveled east-southeast. The first house it came in its way was that of Absalom Vandevere, Swan Township, section 15. He testified as follows: I have reliable information that two or three miles to the northwest clouds were seen rushing south. The clouds came also from the south toward the tornado. Streaks of unusually strong wind seemed to come now and again from the south side and run into the main whirl. The wind on the north side was not nearly as strong as on the south side. Twice as much fence was blown down on the south as on the north side. Its noise resembled that of machinery, only very loud. The dimensions of my house were 36 by 42 by 18 feet.

Samuel Larkins, Swan Township, section 15, witness: Was at Mr. Vandevere's house when the tornado struck it. Heard roaring about fifteen minutes before it came. When I first saw the funnel it did not touch the ground. Saw it whirling contrary to the hands of a watch, and the clouds were drawn in toward it on all sides. It did not lighten before the storm. It lightened a great deal immediately after it passed west. It did not hail nor rain. Did not see clouds in north or south. There appeared to be only a narrow strip of clouds. A McCormick reaper, weighing probably a thousand pounds, was carried ten rods from the south. Two horses were blown, one fifty the other forty yards. An axle-tree, torn from a wagon, was carried a rod and a quarter to the southeast. A shingle was driven through a half-inch ash board. It is in the possession of a Mr. Thomas. A rafter, 8 feet by 2 by 4 inches, was driven through three hogs, and thrust into the ground a foot and a half. All three were dead when it was found. A picture-frame was picked up with the glass unbroken. The wind blew very strongly for about two minutes.



Mr. Vandevere's house, 36 by 42 by 18 feet to the eaves, stood north and south lengthwise. It was moved due north half the length of the house, tumbled over, and blown to pieces. It stood with its north end exactly in the center of the vortex. There were nine persons in the cellar and two in the house. One of those in the cellar was killed by a log. The trees around the house and within the narrow path of the greatest violence, all pointed to the east-southeast, the direction in which the storm was moving.

W. J. Jones, Swan Township, witness: Vandevere's house is forty rods to the east. Myself and wife were in my house when it was blown away. It grew dark as the night just then. There was a little hail before. Did not notice any rain. The storm did not go very fast.

Mr. Jones's house was 22 by 16 by 12 feet to the eaves. It was pushed entirely to the northeast. It then toppled over and was blown to pieces.

The arrow in the sketch should point E.SE.

Sketch of storm-effects at Larkins's, Vandevere's, and Jones's houses.

The fragments in Illinois had already been gathered from the fields, rendering it more difficult to trace the ruins in their flight.

David Smalley, Swan Township, section 22, witness: There was quite a strong wind all day previous to the storm from the southeast. Saw some lightning before the storm. A little hail fell before it and a moderate shower of rain after it. The house stands on the south edge of the storm and was blown east-northeast one inch. It was very warm that day.

Edmund Jennings, Swan Township, section 22, a quarter of a mile south of the center, witness: While the storm was still in the west saw two funnels come together, the one from the north and the other from the south. They appeared to be both whirling, but contrary to each other. When they were still at a distance the sky was cloudy overhead. Their summits appeared to be lost in cloud. Saw lightning and heard thunder previous to the tornado. There fell a little hail before the storm and some rain after it. The trees, chimneys, and fences were thrown down to the northeast.

William Thomas, Swan Township, witness: The center of the storm passed a quarter of a mile to the north. An unoccupied house stood in its way. It was lifted from its foundations and then broken to pieces. Horses were carried a good way and killed. A rail was driven through one of the cattle, going in beneath her tail and coming out at her shoulder. Saw only one funnel.

Robert Wearmouth, Swan Township, witness: The storm-center passed three hundred yards to the north. It was traveling nearly southeast. Horses and cattle were blown a considerable distance. Saw two flashes of lightning before the tornado. Hail fell just before it, and as it was falling heard some thunder. It was so dark when the storm was on us that it was impossible to see anything flying.

Charles Thomas, Swan Township, two hundred yards north of the center and directly north of Wearmouth's, witness: The wind, which blew down trees, unroofed outhouses, &c., came from the northeast and north. Fences were thrown down nearly a mile wide.

Charles Perry, Swan Township, section 24, witness: House, 16 by 24 by 15, with gable-ends facing south and north, was carried to the southeast. There were four inmates, one of whom was mortally injured. Mrs. Perry, who weighed two hundred pounds, was carried one hundred yards and stripped of her clothing. Two horses were carried one hundred yards. Hogs had rails driven through them.

Mr. Perry's house stood near the center of the storm. The west side of the house was blown in and the house instantly broken up.

Caridan Johnson, Greenbush Township, witness: My house is three-quarters of a mile north of the storm-path. Saw no funnel-shaped appearance. Saw some lightning and heard thunder before the tornado came. A few small hail fell before the storm and a very hard rain after it.

B. A. Reid, Swan Township, section 24: Mr. Reid's house stood one hundred yards north of the storm-center. The north side of the house was not blown away, but blown down from the north. The wind had evidently driven in the windows and then burst the house asunder. Hogs, weighing two hundred pounds, were carried two hundred yards.

B. A. Reid, sr., Swan Township, section 25, witness: Saw two clouds, one in the northwest and one in the southwest, rushing together with great rapidity. A whirling commenced right where they met, assuming the form of a funnel. Saw it whirling with the hands of a watch at the distance of about two miles. These low clouds were overhung by a heavy mass of clouds. The funnel reached up to this mass. There was a little hail and a little rain. My house is less than half a mile south of the center.

J. P. Reid, witness, Swan Township, section 25: There was incessant lightning to the northwest before the storm. Heard thunder also. When the storm was one and half miles distant its angle of elevation was about 75°. Saw the funnel distinctly.

H. H. Hewitt, Greenbush Township, section 29, witness: Fences thrown down here over half a mile wide.

P. A. Vaughn, Greenbush Township, section 20, witness: Center of storm passed three hundred and fifty yards south of my house. The strongest gust of wind came on the northeast and north. Three trees, about ten inches in diameter, were carried one-quarter of a mile to the southeast.

Charles McCormick, Swan Township, witnes[illegible] was thrown to the nort[illegible] when three miles distant. A little rain a[illegible]ng, and that it was very [illegible] from the west. There was no wind to d[illegible]ness: My house is forty rods [illegible] south of Swan Creek. Time, about 5.45 [illegible] damaged by a southwest wi[illegible]

H. W. Simmons, Swan Township, se[illegible] farm, on the north side of the s[illegible] passed was about 5.40 p. m. Have [illegible]ant, and on the south side of the [illegible] before its arrival I noticed a very bl[illegible]e line of the storm. There was a[illegible] side of it. My house is three-quart[illegible]ore the storm came up, and lightning [illegible] roaring very distinctly until it w[illegible]., its roar was like that of a cataract. roaring. Then it presented th[illegible]ction 25, witness: Heard no roaring. Hous[illegible] across at the bottom. The top [illegible]o miles of fences blown down; one horse [illegible] the bottom. Did not notice [illegible]oy a rail. hailed a little when it was o[illegible]reenbush Township, section 16, directly nort[illegible] to the south of Swan Creek [illegible] fifty yards to the south of the storm: Wh[illegible]

H. A. Folger, M. D., Yor[illegible]ark, and the roaring was louder than thunder. [illegible] opposite about 5.45 p. m. [illegible]e hail fell and a little rain. The lamp was ligh[illegible]

There were several brig[illegible] Township, Fulton County, section 30, witness: The [illegible] large as bullets fell as [illegible] to the north of the house. Remained out of doors a[illegible] after. It was quite [illegible]appearance touching the ground a half mile distant. The[illegible] strongest gust came, I could not hear the breaking of the building-. There was

In Youngstown [illegible]rting like that of a thousand threshing-machines. Everyt[illegible] was moved from [illegible] thrown toward the center. Most of the wood was deposited [illegible] down, and all t[illegible] storm lay in the northwest a long time, and during that time [illegible] ter of a mile s[illegible] from the southeast. There seemed to be a dark cloud to the [illegible] done by the [illegible] in the northwest, and a clearer space between. The wind blew fro[illegible] almost stro[illegible] the storm passed.

down and [illegible] Union Township, Fulton County, section 30, eighty rods north o[illegible]

After l[illegible]itness: My house is forty rods north of the center of the storm. I[illegible] came in [illegible] the tornado arrived a heavy cloud had been lying in the northwest, tified r[illegible] playing in it. Clouds kept rising in the southwest and passing over [illegible] cloud [illegible]. From the clouds three points came down, from which rain appears [illegible] nado [illegible]. There was clear sky between these points. The ruins of my barn were [illegible] sou[illegible] first a little north, then forty rods west, and then distributed along the [illegible] st[illegible] for half a mile east. They could easily be traced, because the barn was p[illegible] t[illegible] At Joliet Creek, on this farm, the storm either widened or a branch came i[illegible] [illegible] creek. The storm struck us a little before 6 p. m.

J. B. Hatch, Union Township, section 29, twenty rods to the south of the [illegible] center, witness: The storm struck us a little before 6 p. m. As the cloud and dar[illegible] came over, everything appeared to be enveloped in a white mist. There w[illegible] drops, but it wet everything. The carpets in the house had to be taken up and [illegible] The paper on the walls was covered with mud and fine-ground leaves. The sto[illegible] wind came from the southwest. Everything was collected to the center of the [illegible] path. Did not feel any choking sensation when surrounded by the mist. D[illegible] feel cold. Boy felt chilly. It had been a very warm day. Saw lightning right [illegible] storm.

An unoccupied house ten rods south of the storm-center was parted. The kitchen [illegible] carried to the north; the main body to the south.

Cornelius Ackerman, Union Township, a half mile east of Hatch's house and [illegible] rods south of the storm-center, witness: Saw storm gathering in the northwest a[illegible] southwest for some time. Hail nearly the size of hens' eggs fell before the storm [illegible] south wind took the roof off the house. A northwest wind then still further [illegible] ished it. The wind took me off my feet. My hired hand, Cornelius Rice, was [illegible] down by the wind and then pushed along the ground for several rods. He [illegible] his elbow as he went. He first traveled north, and then in a curve round to the [illegible] when he stopped his further progress by clinging to the branches of a tree. [illegible] ground was rather dry before the tornado. It was quite wet after it. Seven [illegible] were transfixed with timbers. A shingle was driven into the sound butt of a [illegible] oak beam measuring 4 by 4 inches. The darkness was black. The direction [illegible] storm-path at this point was still east-southeast.

William McBride, Union Township, section 32, witness: Hail and heavy rain [illegible] fore the tornado. It then became black darkness. Three-quarters of a mile [illegible] from my house chimneys were blown down.

Mr. McBride's house stands apparently near the center of the storm, the[illegible]

Digitized by Google

seems to have mitigated its fury somewhat. The barn-roof was blown to the north-northeast. The barn itself was moved four inches to the south.

R. Johnston, Union Township, section 33: The wind commenced to blow very hard from the south. Went into the cellar. Two small buildings were first blown to the north. The kitchen was blown southeast. The barn and other buildings went south. The main building was pushed a few feet to the southwest. It grew so dark that one could not see ten feet. Some hogs and pigs were carried away, I do not know where. Some of the former weighed two hundred and fifty pounds.

Mr. Johnston's house stood exactly in the center of the whirlwind.

Thomas Poole's house stood to the east of Johnston's. It was demolished. I could not see him.

Andrew Maholland, Union Township, witness: It was near 6 p. m. when the storm struck us. Felt the air to be very hot, like steam, before the storm. The wind at first came strong from the east and was accompanied by a driving wet. The roof of the house was blown to the southwest.

Mr. Maholland's house stands fifty rods to the north of the center.

R. S. Gorham, Union Township, section 33, forty rods south from Maholland's, and rather on the north edge of the center: The house was carried entire a few yards to the northwest, struck the ground, toppled over, and went to pieces. The kitchen was moved a few yards and broke up, leaving the family upon the floor. Trees were blown down from the northeast.

D. H. Gorham, Union Township, section 34, witness: The tornado arrived at my house at 5.55 p. m. Saw the storm gather in the west-northwest one and a half hours before it came. Saw a little lightning as it approached, but none after it arrived. Saw two clouds, one in the southwest and one in the northwest, with a red streak like sunset between them. Afterward saw only one cloud, rolling forward like a wheel. Heard a roaring a little before the storm arrived. It grew so dark that I could not read—a black darkness. First there came a blow from the southeast. After that there came a slight lull, and hail as large as hens' eggs fell straight. Then there came a harder blow from the northeast. Then for three minutes there fell a perfect torrent of rain. Rode out immediately, and the water on the road reached to the horse's belly. My outbuildings were damaged by the northeast wind. Fences were thrown down a mile wide.

Mr. Gorham's house stands fifty rods north of the center of the storm.

A. H. Miller, Union Township, section 35: The house of Mr. Miller stands on the north edge of the storm. There fell a tremendous rain as the storm passed.

At D. M. Kline's farm fences were thrown down a mile wide. They were thrown toward the center from both sides. The storm at this point had greatly diminished in violence.

O. Chatterton, Lee Township, section 1, witness: Heard the roaring only a few minutes before the storm came. The wind blew first from the southwest, then from the northeast, and then from the north. Saw no lightning. A tremendous rain fell about eighty rods south from the house. Thinks that this heavy rain did not extend far south. The Council Corner school-house was turned round.

John Schneider, Ellisville Township, had some fences blown down on the northwest bank of Spoon River.

H. Caril, village of Ellisville, witness: A very heavy rain fell during three-quarters of an hour. For six miles to the north everything was flooded. There was not much lightning. Heard a roaring, but not very loud.

Isaac Sechleider, Deerfield Township, section 7, across Spoon River: Mr. Sechleider's house stood near the summit of the bluffs which face the river. It measured 16 by 22 by 12. It was blown southeast three rods, and deposited on its roof. The five inmates were not much injured. The storm smashed the timber somewhat on the southeast bank.

About a mile farther on it became impossible to track the storm. Before proceeding to where it next struck, it may be advisable to insert some testimony from Prairie City and the neighborhood. Prairie City is about one and a half miles south from the storm-path.

The editor of the Prairie City Herald testified that he thinks the storm was opposite a little before 6 p. m.

C. H. Hemenover, Prairie City, testified that oak-leaves fell during the storm, and that the wind blew very strongly from the south. He keeps a thermometer, but did not look at it that day. Thinks temperature was not over 70°.

L. B. Day, Prairie City, witness: Saw a cloud in the northwest of a funnel-shape; heard a roaring sound for perhaps five minutes. The wind blew strongly from the southeast all of a sudden, accompanied with hail about the size of pigeon-eggs. There was an undercurrent of clouds from the southeast overhead. Just as this southeast wind blew it grew very dark. After the tornado passed the wind changed to the northwest, and a smart shower fell. Then it cleared up, and the sun shone.

J. M. Kershaw, hotel-keeper, Prairie City, witness: It grew dark about 6.05 p. m.

Digitized by Google

saw clouds from southeast sent a-whirling as they struck the northwest clouds; saw continual lightning as the storm approached; heard roaring after the storm passed.

J. H. Day, Lee Township, about one mile south of the center of the storm, witness: There fell a very heavy rain, with north wind, so heavy as to flood everything in a minute. It filled a small creek so that I could not get home that night. I was one-half mile farther south than my house. The windows were smashed with hail on the north and east.

Wm. Henry, Lee Township, section 4, witness: Saw a heavy cloud in the northwest and a less heavy one in the southeast. There was a lighter space between, but could not see the sky there. The wind blew first from the east, and damaged the outhouses. Afterward there came a northwest wind, with a terrible rain.

Samuel Taylor, Lee Township, section 20, four miles south of storm: It rained a little from southeast, and then the wind came more from the south.

A. T. Irvine, station-agent, Prairie City: The telegraph was not disturbed by the electricity during the passage of the tornado. It only ceased to work between this and Avon after the wires were broken by the wind. The wind blew from the southeast as the storm approached. It rained quite a while from the southeast. Then it changed to the southwest, still raining, and when the rain somewhat ceased, it came from the northeast.

H. M. Torseman, Prairie City, witness: Between Ellisville and three miles north of it, there fell a most tremendous rain. Logs and rails were carried into the roads by the water.

Having learned that the tornado had made another descent at Utica, near the Illinois River, I proceeded thither.

Jacob McCan, Utica, Banner Township, Fulton County, witness: Storm came at 6.30 p. m.; saw lightning and heard thunder in the northwest, where a heavy cloud had long been gathering; saw two under-clouds, one in the southwest and the other in the northwest, moving toward each other. They were wind-clouds. Above them was a dark-green cloud. The two clouds were whitish, and were boiling up. The sky to the east was clear at this time, the storm coming up as an isolated, solid mass of cloud. The wind commenced to blow hard from the southwest. Then there came a brief lull; then a second blow from the northwest. With the northwest wind there came a cloud of smoke. It came in through the broken window. It came right in the fury of the gale. It was all dark in front of the window with it. This northwest wind was pretty cold. It hailed a little before the storm, and it rained very hard after it.

Nearly all the houses in Utica were more or less damaged, and several were blown down. The village stands on the bottom-lands of a small creek running into Illinois River. High bluffs rise all around. The tornado was here traveling southeast. It came down about one-half mile to the northwest of Utica. It continued to overthrow trees until it reached Illinois River, which is distant from Utica about one mile. It then turned abruptly to the northeast, traveling up the stream, which it then followed for about fifteen or more miles in a straight line, but much farther counting the bends in the river.

Charles Rice, Fulton County, Banner Township, one and a half miles from Illinois River, just at the commencement of the wooded swamp bordering the river, witness: The wind blew down two trees in my orchard. It was a north wind. The storm center was at least one-half mile nearer the river. There were a few hail at the commencement, and a heavy rain afterward.

M. B. Murray, Peoria County, Timber Township, section 31, and one mile distant from the river: The storm blew down a great deal of timber along the banks. Some trees were also blown down on the other side of my farm, on the summit of the bluff. A heavy rain immediately followed the wind.

A. King, Peoria County, Timber Township, section 31, witness: My house is one and a quarter miles from the river to the northwest. My fences were blown down.

A. Dempsey, village of Kingston, Peoria County: A few chimneys were blown down in the village, and similar damage done. Two cows were killed by lightning. Some timber on the river was blown down.

Kingston is situated on the bottom-lands of the Illinois River, and close to it.

Mapleton, Peoria County: Here there fell hail as large as hazel-nuts, and a very heavy rain, accompanied by thunder and lightning. It occurred after 6 p. m. William Harrison testified that he saw trees in considerable numbers which had been blown down in the storm of May 22.

Pekin: The ferryman testified that there was a big rain-storm with high wind. The smoke-stack of his boat was somewhat damaged by it. Mr. Tazewell stated that the high wind came first, then the hail and rain.

Fred. Netz, Washington, Illinois, witness: It blew very hard about 6.15 p. m. There was a heavy rain.

Thomas Handsacker, editor of the Washington Herald, Washington, Illinois: The storm came at 6.10 p. m., or very nearly. I watched the cloud. Did not see any funnel appearance nor any whirling. There was a very heavy rain, accompanied with hail.

Digitized by Google

der and lightning. The wind blew down numbers of trees in different directions, but mostly from the southwest. Heard that at Eureka there was a considerable storm.

I accordingly went to Eureka, but found nothing of importance. Before closing the statement of facts, a few data may be adduced, showing the widely-extended area over which the storm, or portions of it, manifested itself:

Special dispatch to the Chicago Tribune.

OTTAWA, ILLINOIS, *May* 23.

The tornado which passed through Central Iowa seemed to have spent its force here last evening. An enormous quantity of rain fell in an incredibly short time, and the trains on both railroads were delayed for hours. Bridges were swept away and much damage done. Ottawa lay directly in the line in which the storm was traveling when I ceased to follow it.

Special telegram to the Chicago Times.

SPRINGFIELD, ILLINOIS, *May* 23.

A very heavy storm of wind, rain, and hail passed over this city last night.

Special telegram to the Chicago Times.

PEORIA, *May* 24.

The severe storm of Thursday night did much damage in Princeville, this county. A narrow strip of wind passed through Southern Village, almost literally demolishing the house of Oliver Moody.

The following is an extract from a letter by B. Whitaker, chairman of the meteorological committee, who resides two and three-quarter miles east of Warsaw, Illinois, in correspondence with the Chief Signal-Officer:

"On Sunday, May 22, about 3 p. m., or perhaps a little later, while planting potatoes in the field, a roaring noise was heard a little west of north. Being familiar with the noise of railroads, steamboats, &c., was at a loss to account for it. We stood and listened five minutes. The continued roaring noise indicated great force. A perceptible indication of its moving more to due north was manifest. After resuming our work the noise was heard for some time—ten or fifteen minutes or more. A dark cloud occupied the heavens in that direction, the point or foremost end moving to the northeast. The motion of the cloud was not easily indicated, on account of intervening and adjacent clouds. My place of observation is two and a half miles due south of the signal-station Keokuk, and two and three-quarter miles due east of Warsaw, and the distance to the path of the hurricane at least sixty miles."

Mr. Whitaker adduces a number of names of respectable parties in support of his remarkable statement as being co-witnesses.

Such is a statement of the facts connected with the Iowa and Illinois tornado of May 22, 1873, so far as I have been able to collect them. I spared no pains in order to render it scientifically complete, sometimes traveling miles under a fierce sun, and with a temperature among the nineties, in order to obtain the evidence of one man. The information given by any witness by no means represents the number of questions asked him. These were extensive and calculated to extract all the knowledge on the subject possessed by those under examination. For instance, the following question was addressed to all and sundry: Did you observe any pointed objects, such as lightning-rods, posts, &c., tipped with flame, during the progress of the tornado? But being uniformly answered in the negative, has not been formally inserted in the statement of facts. Also, a description of the sound was exacted from all witnesses, but only a few typical ones have been inserted. I regret this at present, because I have learned from experience that very important questions may attach themselves to a description of the sound. While interrogating parties the utmost vigilance was exercised to prevent them from giving conclusions for what they saw and heard. This was a very troublesome point, and caused the interrogator to appear in many cases in the highest degree rude; while it also excluded from these pages the names of persons who observed accurately, but who are unable to distinguish between the *esse* and the *ergo*.

No opportunity was allowed to pass of obtaining information. Whether at home, on the road, or in the field, all met were questioned. Of course by far the majority could give no information worth taking.

It will be noticed that the statement of facts for Iowa is much more exhaustive and instructive than that for Illinois. There are several reasons for this:

1. Some weeks had already elapsed since the tornado, and its traces were becoming rapidly obliterated, both in the memories of the witnesses and upon the surface of the earth.

2. It was later in the day when it occurred, thus hiding the light of the sun more

Digitized by Google

completely by the tornado-clouds as they approached, and rendering it more difficult to observe accurately their forms and proportions.

3. The storm in Illinois seems to have been of a somewhat different character from that in Iowa, by its form rendering observation more difficult.

It may perhaps not be deemed irrelevant to mention that the best information was uniformly obtained from those who are not natives of the localities in which they live, but have settled there from other States or other countries. The reason of this may perhaps be that Iowa and Illinois are but recently settled, and that consequently the native-born population have not yet had time to arrive at years of discretion, whereas the original settlers are in the prime of manhood or verging toward old age.

With regard to the angles of elevation given, it must be borne in mind that they are only approximations. Very few indeed of the witnesses have accurate conception of angles. I generally made them point in the direction in which an object was seen, and so estimated the angle.

CALCULATIONS AND CONCLUSIONS.

The idea of a tornado in general.

The tornado consists essentially of a rapidly-ascending current of air. This involves two other functions: first, a rushing in of the air at the under part of the ascending current or column; secondly, an outrushing at the upper. Upon the former of these functions, combined with modifying circumstances, depends the peculiar character and career of the undercurrents and of the clouds they bear; upon the latter, combined with the same circumstances, the proportions and direction of motion of the upper currents and of the heavy masses of clouds they bear. There appears to be nothing in the nature of the tornado itself which can determine the motion of either the upper or under current more toward any one point of the compass than toward the others. The direction of motion relative to the ascending column depends upon the direction and velocity of motion of the latter, and of the atmospheric strata in which the influx and efflux take place, modified, to some extent, by the differing velocities of revolution of the surface of the earth at different parallels of latitude, by the form of the earth's surface, and by the variation in the constitution of the atmosphere. If the tornado column, and the atmospheric strata which it penetrates, move in the same direction and with the same velocity, the influx and efflux will take place in nearly equal quantities on all sides of the column. If they move with different velocities the direction, exaggeration and diminution of the influx and efflux can be calculated in the same way as the direction of a wind-vane on a ship's mast, giving the directions and velocities of the motion of the wind and of the ship.

General idea of the tornado of May 22, 1873, in Iowa.

A huge, dark cloud covered an area at least thirty miles in diameter. Under the southwest edge of this cloud there moved a perfectly opaque funnel-shaped appearance, reaching from the ground to the clouds. Toward its base, the wind, in spirals, rushed violently from all sides, overthrowing, when in immediate proximity to it, within the opaque vortex, whatever opposed its progress. Toward its summit, where it disappeared in overhanging horizontal cloud, long streaks of clouds rushed in spirals from all directions. Viewed from a distance they appeared to come from opposite directions, and move swiftly toward each other at right angles to the observer's line of vision. Between the surface-current and these centripetal clouds the air doubtless obeyed the same forces, and rushed in spirals with ever-increasing velocity toward the opaque funnel.

Under the remainder of the lofty cloud which defined the limits within which the outspreading of the ascending air was taking place, and which lay chiefly to the northeast of the rising column, there raged a tremendous storm of hail and rain accompanied by incessant and brilliant electrical phenomena.

More particular description.—Dimensions of the meteor, and of the centrifugal or upper current.

Mr. B. Whitaker, (p. 1081) when sixty miles distant, saw the summit of the dark cloud in the direction of Washington, Iowa. Of this fact there can be little doubt, the time agreeing precisely. In order that its summit might barely reach the level of the rational horizon the cloud would require to have an elevation of $\sqrt{(4000)^2 + (60)^2} = 4000$ mile nearly. Mr. Whitaker simply states that a dark cloud occupied the heavens in that direction. This supposes that it reached to a considerable distance above the horizon. If we suppose it only reached 15° above it an additional elevation of one

Digitized by Google

sixteen miles, or a total height of between sixteen and seventeen miles, would be required.

Mr. Whitaker's evidence as to the immense height of the cloud receives corroboration from the evidence of a great many of the witnesses, who state that they saw the black cloud in the west for hours before the tornado came. Since the storm traveled thirty miles per hour, if the cloud was seen two hours in advance at an elevation of 15° above the rational horizon, and it would scarcely have attracted attention when lower, then it must have been sixteen miles in height.

The data for determining the horizontal extent of the cloud are not very precise. There is a general concurrence of the witnesses that it reached only a few miles to the south of the tornado, and that very little rain or hail fell there. G. W. Brockway (p. 1072) testified that at Talleyrand, about two and a half miles southeast from the track of the tornado, there fell neither hail nor rain, and that the cloud did not reach the zenith. Isaac Farley (p. 1071) testified that at Foote, Iowa County, fifteen miles north of Talleyrand, there was but little rain and no hail. E. R. Eldridge (p. 1071) testified that at Washington the cloud reached a little beyond the zenith. At Lone Tree and Nicholl's Stations I found by personal inquiry that there was a very heavy thunderstorm. These stations lie eighteen miles north-northeast of Washington. It is evident, moreover, that the cloud must have extended considerably beyond the area over which it rained. It is probably, therefore, no exaggeration to assign thirty miles as the diameter of the cloud from south-southwest to north-northeast.

Arthur Howell (p. 1071) testified that at Yalton, five miles north of the tornado, three fell a heavy rain of about an hour's duration. The storm traveled about thirty miles per hour. This would give the cloud an extent in the direction in which the storm traveled of more than thirty miles. There is a general agreement among the witnesses that a little hail fell some few minutes before the advent of the funnel, and a little rain immediately after its passage. The whole appears to have occupied at least thirty minutes in passing. This would give the cloud at the funnel a width of at least fifteen miles in the line of its progress. Probably it was considerably greater. We may, therefore, safely conclude that we are within the limits when we assign to the centrifugal cloud an average horizontal diameter of thirty miles.

I have no data for determining the elevation of the under side of the centrifugal cloud beyond what is involved in those for measuring the altitude of the centripetal. There must, however, have intervened a very considerable space between the two. For if there was nothing intervening there could be nothing to prevent the under, and specifically lighter, air from taking the shortest way up. There could be no reason why it should first rush to a center, ascend there, and then rush from it.

Dimensions of the centripetal current.

The data for determining these are still less precise than the preceding, but yet sufficiently so to give a more definite idea than any mere description in general terms.

H. C. Vittitoe (p. 1071,) saw, when three miles to the northwest of the tornado-path, white underclouds rushing to a center a little south of the zenith. A. Vandevere, whose evidence may be here adduced, although it refers to the tornado in Illinois, states: I have reliable information that two or three miles to the north the clouds were seen rushing south. The clouds came also from the south. Nearly all the witnesses who watched the approaching storm tell of clouds seen darting toward each other from opposite directions. It was impossible, however, to obtain anything like accurate measurements, owing to the distances being unknown. If we suppose that the centripetal clouds had a horizontal diameter of four miles, we may obtain a determination of elevation from the data given by E. R. Eldridge, (p. 1071.)

At four miles' distance, the point where the lower clouds seemed to join the higher appeared to him to have 35° of elevation. Deducting two miles from the distance for the assumed diameter of the centripetal clouds, we have an elevation of 1.4 miles.

J. W. Plumber (p. 1062) gives the angle subtended by the centripetal clouds when several miles distant, at about 45°, and the angle of elevation at about 35°. If we assume the distance to have been five miles, we should have over 4.6 miles as the diameter of the centripetal clouds, and 3.5 as the altitude, which latter figure is, perhaps, though not necessarily, too great.

The assumed distance of five miles refers to the base of a perpendicular from the summit of the cloud to the ground, and it is probably not too great since it corresponds to only ten minutes' motion of the storm. These clouds attracted attention by the great rapidity of their motion toward a common point; but their velocity gradually diminished from the center to their outer limits. They undoubtedly commenced the journey with a velocity by no means striking, and in much smaller and less dense masses. Hence the probability is that they extended much farther than they were observed with sufficient attention to leave an impression upon the memory. Moreover, the current in which they originated must have been in motion toward the vortex before they were formed, because they owed their existence to the circumstances con-

Digitized by Google

nected with that motion. It is, therefore, probable from these data that in assigning ten miles as the diameter of the centripetal current at the altitude of these clouds we do not overrate it.

There is good reason for believing that the diameter of the centripetal current was not less at a considerable elevation than at the earth's surface, because of the many obstacles there opposed to its progress. Yet R. L. Harper testifies that, at Baden, three miles northwest of the storm-center, the wind changed from northeast to northwest as the storm passed. This implies that it blew at least some few minutes from a northerly direction, and also with force sufficient to attract attention. Suppose it blew 20 minutes in all from a northerly direction, we should have, since the storm was traveling thirty miles per hour, a diameter of nearly twelve miles for the surface centripetal current.

It is here necessary to the force of the reasoning to call attention to the fact that the wind, on the 22d of May, was, in accordance with the barometric gradient, southerly.

William P. Lisk (p. 1048) states that about twenty minutes before the arrival of the tornado the wind blew from the north. This would give a diameter of twenty miles, that is, assuming the northwest quadrant to be as extensive as the northeast.

M. Williams, (p. 1048,) a very careful witness, states that about twenty-five minutes after the passage of the whirlwind, the wind came again from the southwest. This also gives a diameter of twenty miles. The witnesses (see Keota evidence, &c.) generally testify that hail fell from 15 to 30 minutes before the whirlwind, and rain for as long a period after. They further, almost unanimously, say that the wind was easterly with the hail and westerly with the rain. If we assume 20 minutes as the duration of each of these winds, we again obtain twenty miles as the diameter of the inrushing winds at the earth's surface.

If the disturbing influences were not much greater at the earth's surface than at a higher altitude, the dimensions of the whirl should, within the limits of the centripetal wind, owing to the absence of friction, vastly increase as we ascend. Moreover, since the funnel was first formed at a considerable elevation, and since it touched the ground with a narrow point, and merely incidentally, as it were, since it for long distances ceased to strike the earth, and yet proceeded with undiminished energy; since, in short, both the originating and sustaining sources of its power seem to have mainly existed high in the atmosphere, we have the strongest reasons for concluding that the horizontal dimensions of the centripetal current were very much greater at its more elevated portions than at its base. It would therefore appear to be not unlikely that the diameter of the centripetal current was not greatly exceeded by that of the centrifugal.

Since writing the above I have received a communication from Frank McClintock, correspondent of the Smithsonian Institution, West Union, Iowa. He states that there was a thunder-storm in the morning and another in the afternoon; that the wind changed from the south to the west rapidly at 3.45 p. m., and that it worked back to the south before 9 p. m. This change of the wind agrees with the time at which the tornado passed Washington, Iowa, allowance being made for the interval which must elapse before the atmospheric disturbance could travel over the one hundred and twenty intervening miles. This change of the wind may, however, have been due to the thunder-storm mentioned. We are not, therefore, entitled from this solitary instance to conclude that the tornado had a radius of one hundred and twenty miles, although it renders it somewhat probable that it did.

The following is also a late communication. Capt. J. W. Stewart, of the steamboat Victory, states:

The tornado occurred opposite Buffalo, Iowa. The time was approximately about 4 p. m. The sky-light, pilot-house, and chimneys were blown overboard. The wind came in three heavy gusts, accompanied by very heavy rain, in fact, almost a waterspout, and the darkness was intense. The duration was not more than five or seven minutes.

The dimensions of the funnel.

The height and size of the opaque funnel varied, as seen by the eye of an observer. At times it barely touched the ground with a narrow point, at others it stood on a broader base, while for long distances it ceased to touch the ground altogether. The clouds into which its summit disappeared, appear not always to have preserved the same elevation. These changes, however great they may have seemed to the eye witnesses, are yet in themselves insignificant when we realize that this funnel-shaped phenomenon was the base of an ever-widening column ten to fifteen miles high.

The data for calculating the dimensions of the visible portion of the funnel are more numerous than precisely accurate. In criticising them, it is to be remembered that the apparent height depended not merely upon the distance, but also upon the fact that on account of the inclination of its sides a greater portion of the funnel was seen by observers at the distance of a mile or two than by those nearer.

Digitized by Google

To Mr. R. L. Jay, the funnel when three miles distant appeared to be about one-fourth mile high.

M. Williams (p. 1048) states that when the funnel struck the ground the fences for 60 yards were carried away. It does not appear probable, however, that the base of the funnel was 60 yards wide at this point. But suppose we assume that it was, and also assume that the width of the summit was five times that of the base, which his description warrants. When at the distance of 300 yards the angle of elevation was supposed to be about 75°. From these data the distance of the witness from the base of a perpendicular from the edge of the summit would be 180 yards. This gives an elevation of 672 yards.

Sam Brunt testifies (p. 1049) that the breadth of the funnel, when on his farm, appeared to be about 100 feet.

Wm Davis (p. 1050) places the angle of elevation at 15° when half a mile distant. This gives an elevation of 235 yards.

Fred. Tollman (p. 1050) at 70 yards distance estimated the angle of elevation of the summit of the lower funnel at 60°. This gives an elevation of 121 yards.

Matthias Gengler (p. 1052) from an elevation of 200 feet and a distance of one mile estimated the angle at 55°. This gives an elevation of 2,580 yards.

Matthias Hotel (p. 1053) viewing it from the same distance and direction, but from a lower level, gave the angle at from 55° to 60°. This may be regarded as identical with the last.

Eli Walker (p. 1053) gave 30° at the distance of one and a half miles. Hence we have an elevation of 1,524 yards.

E. Stout (p. 1053) one and a half miles, 15°, and elevation of 707 yards. This refers only to the lower funnel.

Rev. J. P. Coffman (p. 1060) one mile, 25°, and elevation 821 yards.

F. Brown (p. 1061) one and a half miles, 15°, and elevation 707 yards. Mr. Brown estimated the breadth of the top at five times that of the base.

J. W. Plumber, (p. 1062,) three-fourths mile, 25°, and elevation 615 yards.

John Maughlin, (p. 1062,) 200 yards, 15°, and elevation 54 yards.

R. M. Stevenson, (p. 1063,) 700 yards, 35°, and elevation 490 yards.

The smallest of the results is 53 yards, and it may be safely discounted, because, at the distance of 200 yards, the darkness was great and the wind very strong. The time for observation also in such a position, with the storm directly approaching, was brief. The most reliable results are those obtained from observations taken on the south side of the storm-path, and at a distance of at least a mile from it. There the base-line could be accurately determined, and ample opportunity was had for calm observation. I therefore value the data on the subject of elevation afforded by Matthias Gengler and Matthias Hotel above all others. Their elevated positions gave them a splendid opportunity of watching the magnificent spectacle. The tornado was moving steadily along North Skunk River, without jumping up and down and skipping from side to side. Eli Walker and E. Stout, while occupying a position otherwise good, could not so well determine the distance of the meteor, because it was approaching them. Besides, the figures of E. Stout refer only to the lower funnel. These four witnesses watched the meteor at the same time. I therefore conclude that the tornado column was, from a favorable position, visible at some parts of its course to a height of between one and two miles.

In this connection it should be remembered that the data furnished by E. R. Eldridge (p. 1071) gave an elevation of one and a fourth miles to the cloud which he saw bending forward, but did not recognize as funnel-shaped.

Wherever there was evidence of the funnel having touched the ground there was, to a greater or less breadth, what I have designated as the vortex of extreme violence, varying from 100 yards in breadth to nothing. Without having positive evidence, and notwithstanding that there was everywhere a gradual diminution of violence from the center to the circumference except in the remarkable phenomenon of streaks or arms, and no abrupt transitions, I could not help concluding that the path of greatest violence was identical, or nearly so, with the diameter of the base of the funnel when it touched the ground. This would give it an average diameter of about 30 yards. The witnesses are generally agreed that the summit was several times wider than the base. The exceptional case in which two funnels are superimposed will hereafter be treated. If we assume that the visible top was five times the diameter of the base, we have, say for the altitude of one mile, a diameter of only 150 yards. I think, however, that, owing to its great elevation and the optical delusion connected therewith, and the general belief of the spectators, the funnel was, at the very utmost, only a few hundred feet high; the diameter of the summit was very much greater.

The changes seen in the funnel.

Some observers saw only one funnel; others saw two funnels superimposed, with the narrow ends together, and the smaller one beneath; while a good many saw two

Digitized by Google

and even three funnels, side by side. The evidence on all these points is beyond question. At first I was inclined to believe that two or more funnels had actually touched the ground and traveled side by side. The sketch of the storm by R. J. Cambell seemed to favor this explanation. It shows a protuberance on each side of the funnel, which looks like an inceptive funnel. The fact that a second funnel should travel along on the southeast side of the main one without disturbing the symmetry of the action of the latter, as exhibited by the ruins, did not appear altogether incredible, for it is abundantly evident from the statement of facts that the damage was done by a wind blowing in the path of the tornado when the black funnel hovered above or slightly touched the ground. Thus an incipient funnel, moving along the southeast side of the main funnel, and occasionally making a dip, would produce no appreciable discord in the disposition of the ruins. An insuperable objection to this theory was found in the unanimous testimony of the eye-witnesses that the funnels approached each other and combined to form one. Another objection was found in the lack of unity thus introduced into the conception of the magnificent whole. Finding this explanation untenable, I endeavored to think the possibility of smaller auxiliary funnels, each of the a perfect whirl, moving in spirals nearly or altogether identical with those pursued by the confluent winds. This I found to be more difficult than the first. The chief objection was the total lack of a conceivable cause of the existence of these smaller whirls. The second was the peculiar circumstance that while one observer saw two funnels, another in the same position saw only one, or saw two superimposed with the smaller ends together. No possible arrangement of two independent funnels with the smaller ends down could produce the optical illusion of two funnels superimposed with the smaller ends together. I found what I believe to be the key to the difficulty while considering Mr. Marbourg's delineation of the two funnels joining in one tube. (p. 1065.) The other observers who saw two or more funnels evidently had the whirl of their attention confined to these, and did not observe what was above them. Hence the two combine at what he estimated an altitude of fifty feet and form one. Another witness, at the same place and time, saw only one funnel. At Lancaster, some saw only one, others saw two superimposed, and others saw two side by side, and all at the same time. There was, therefore, an unavoidable necessity for some explanation which could reconcile these antagonistic appearances.

Explanation.

There is excellent evidence to show that the funnel moved at its base with a sort of pendulum motion; that it seemed to stand still for a moment and then to bound suddenly forward. The evidence on this point is so general that we need not recapitulate it. But we have no reason for supposing that this oscillating motion extended to any considerable distance above the ground, for it is only in the want of homogeneity in the atmosphere and the resistance opposed to the free course of the winds by the earth's surface, that we can find a cause for this pendulum motion. Let us suppose that the funnel is over a well-watered and well-wooded ravine, with its path at right angles to it. It is evident that the air at some distance above the ground will find much less resistance to the forces drawing it into new paths than that on the surface, where the friction is so important an element. In the forward march of the tornado the base would thus be somewhat left behind. The warm, moist air of the ravine would increase this tendency, on account of its specific levity. The funnel would become bent thus:

But the inrushing winds follow the path of least resistance toward the area of greatest rarefraction. The bending, therefore, cannot proceed far, for the southwest winds, whose direction of motion is carrying them away from the base of the inclined funnel, will find less resistance and a shorter path toward the greatest rarefaction, by striking up into the nearest point in the side of the funnel.

A streak of rarefaction great enough to produce condensation is thus generated. This arm of the funnel, affording the shortest way for the winds, will increase in rapidity. The other will decrease, becoming mainly confined to the northwest side. Meanwhile the intervening air will become rarefied and set in motion; the two arms will suddenly unite, and the funnel present again its original proportions. These transformations must take place within a brief space of time, for the tornado is traveling at the rate of half a mile per minute. When we consider, in addition, the darkness, we will be at no loss to conceive why these two branches should present the appearance of one funnel with its smaller end down, and why, to a less favorably situated or more superficial observer, the whole should appear as one.

One difficulty yet remains to be obviated. Since the arm moves forward in a curve to the center, and the velocity of the inrushing winds at the funnel far exceeds a hundred miles per hour, how is it possible for the observer, in the darkness, to see the appearances distinctly? Mr. Marbourg gives the distance between the two arms

Digitized by Google

at 200 feet. This space would be traversed in one second by winds of so great velocity, and the condensed vapor would fill the whole space before it had time to disappear. The very velocity itself would render distinct vision difficult. We must not, in short, confound the path of the winds with the winds themselves. While the winds were rushing up in a slanting and curving direction along these arms, the arms themselves might be moving forward with a much less rapid motion. If it were possible to determine the inclination of these arms to the perpendicular it would aid in calculating the force of the wind. Mr. Marbourg stated that the distance between the bases of the two arms was 200 feet, and the height, when they joined together, 50 feet. He gave 80 to 100 feet, however, as the height, to the editor of the Washington County Press. His own delineation favors the belief that the height was greater than 50 feet. He could easily judge of the distance between the arms, but was very liable to be mistaken in estimating the height. The error, therefore, will probably not be great if we assume that the funnels joined together at the height of 100 feet. This would give these arms an inclination of 45°.

The direction in, and the velocity with which the tornado traveled.

From its starting-point on South Skunk River until it reached North Skunk River, a distance of ten miles, the tornado traveled in an east-northeast direction. It then turned a little south of east and followed the course of that river for two miles. It then went east-northeast until it came to Rock Creek, when it turned a little west of north and followed the course of the creek for a short distance. It then traveled northeast until it ceased to touch the ground three miles from Keota. After lifting itself from the ground it traveled about east-northeast, striking again at Westchester, Washington County. From this point until it reached Enoch Wright's, a distance of over nine miles, its course was nearly straight, varying between northeast and east-northeast. Its course then became very crooked, bending in curves from northeast to southeast, and *vice versa;* but on the whole traveling east until it came within a mile of the confines of Washington County, when it made a decided turn to the southeast. Here its path lay down the declivity toward the well-wooded ravine of Goose Creek. When within half a mile of the creek its traces became so feeble that it was impossible to track it farther. It was at this point, within one and a half miles of Iowa River, the course of which is here nearly parallel with that of the tornado. The crookedness of its path reached its maximum within the last half mile of its career, before ceasing to touch the ground, as a black funnel at A. Davidson's farm, Highland Township. Within this half mile it bent first a little to the southeast, then to the northeast, then to the southeast, and again back to the northeast, when it disappeared.

After leaving Crooked Creek, at the commencement of its career in Washington County, and until it reached to near Goose Creek, the tornado traversed an elevated, well cultivated region, almost totally devoid of trees and water-courses. There was apparently nothing in the configuration of the ground over which it passed which could account for its changes of direction. These changes, moreover, were not generally abrupt, the tornado sweeping in graceful curves from one direction to another. It is to be noted, however, that the curving of its path commenced after it came within the influence of the moister, warmer air of the Iowa River, and that the general deviation of its course from the northeast direction, which it had on the whole hitherto followed, led it down the valley of the Iowa River.

In order to determine the velocity with which the meteor traveled, it was necessary to obtain the precise time of its arrival at different points. The difficulty of obtaining precise time in an agricultural district is always considerable. In addition, no one thought of looking at his clock or watch; hence, although every witness was questioned on this point, there were but few who could even approximate to the time. The majority thought that they had a remarkably definite idea when they could tell between what hours it occurred. Reliable time, it is believed, was obtained at least at two places in Iowa, at Wolfden school-house, Lancaster Township, Keokuk County, and at A. McKee's house, section 23, Cedar Township, Washington County. The times obtained at these places were corroborated by the testimony of those likely to be best informed. The tornado struck the school at 2.15 p. m.; it arrived in section 23, Cedar Township, at 3.10 p. m. The distance between these places in a straight line is twenty-seven miles. This gives a velocity of 29.4 miles per hour. The crookedness of its course, though not great, would bring its velocity along its path to thirty miles per hour at least.

The direction of the centripetal winds.

The wind blew in spirals toward the center of the vortex, the direction of revolution being contrary to the hands of a watch throughout the whole course of the storm. The evidence in support of this, as given in the statement of facts, is overwhelming, and recapitulation unnecessary. The mere fact that all who had an opportunity of

Digitized by Google

seeing the funnel saw that it was circular is sufficient to prove that it was a whirlwind, for on no other hypothesis could the circular form be accounted for. Then the witnesses, almost without exception, saw this funnel whirling contrary to the hands of a watch. Then the illustration of the position of the ruins of the houses and of the fallen trees, &c., proves beyond a doubt that a merely centripetal wind could not have done these things. Again, that the wind was not blowing in circles round the center is sufficiently demonstrated by the fact that everything, except within the most violent vortex, was thrown toward the center. The ruins invariably lay most thickly there. The only form of motion capable of producing these effects is a mean between the circular and the direct centripetal, to wit, the spiral. The illustrations give copious ocular demonstration that such was the case. The ruins of houses, whenever they could be distinctly traced, proceeded in a curve toward the center, which apparently was always reached before the completion of an entire revolution. This does not imply that the centripetal winds never performed a complete revolution before reaching the center, but only that from within about 100 yards of the center this did not take place. Ruins carried from that distance seemed generally to reach the center in about two-thirds of a revolution. This led me to assume that at about 100 yards from the center the wind generally made an angle of about 25° with the tangent. This gives a centripetal component compared with the circular as .42262 is to .90631.

Besides its horizontal motion, the wind had necessarily an ascending motion, which reached its maximum at the center and its minimum at the circumference. The necessity for this lies in the proof of the centripetal motion of the wind; otherwise the centripetal motion of the wind would require to double itself at half the radius from any point toward the center. This would soon give it a motion infinitely great, which is absurd. There would also be no means of escape for it at the center. We have, besides, ocular demonstration. To a great many excellent witnesses the funnel presented the appearance of a screw with its thread running upwards. In addition, all objects within the sphere of the tornado seem to have been partly lifted, partly pushed forward. We have seen that at A. Gibson's house the arms made an angle with the perpendicular of probably about 45°. Since these arms, as there is every reason to believe, were inclined in the normal direction of the winds, which is that of least resistance, we are justified in assuming that in the black funnel itself the inclination of the winds to the horizon was at least as great, and probably greater.

The velocity of the wind.

This is a very difficult topic. The task would have been much easier if we had been dealing with a horizontal wind merely. If even the perpendicular and horizontal components were invariable, the hope of a tolerably accurate solution of the problem would be much greater; but while the former decreases from the center to the circumference, the latter increases. Neither is it possible to do more than approximate to the relative strength of these components at any point. In order that no chance of a solution might be lost, I collected the following heterogeneous data:

1. A school-house, weighing 30,000 pounds, was pushed 25 feet from its foundations. The surface exposed to the wind = 360 square feet + the roof, which had a slant of 45°, (p. 1049.)

2. A beam, 14 feet by 2 by 4 inches, weighing 25 pounds, was carried 35 yards, and driven into black mold 3 feet 9 inches, at an angle of 35°, (p. 1050.)

3. An iron sausage-machine, 6 by 8 inches greatest exposure of surface, and weighing 15 pounds, was carried away, (p. 1054.)

4. An oak tree, 3 inches in diameter, was perforated by a board 6 by 1 inches and (probably) 8 feet in length, (p. 1057.)

5. A hog, weighing 400 pounds, was carried a mile and a quarter. A cow and horse were carried 400 yards, (p. 1058.)

6. A horse-power machine, weighing 2,400 pounds, and exposing a surface of 2 square feet, was pushed forward 6 yards, (p. 1058.)

7. A post, 8 feet long and 4 inches in diameter, and which had been driven 3½ feet into the soil, was pulled out by the wind, (p. 1059.)

8. An elm fence-board, 8 feet by 6 by 1 inches, was driven into the soil 4 feet, at an angle of 45°, (p. 1060.)

9. A door, exposing a surface of 18 square feet, was held by four men against the wind, (p. 1063.)

10. A house, exposing 280 square feet to the wind, having a floor of 480 square feet, and weighing 20 tons, was pushed 6 feet from its foundations. It was then lifted over the tops of trees 20 feet high, (p. 1063.)

11. A heifer weighing 700 pounds was carried away, (p. 1063.)

12. A house presenting to the wind a surface of 176 square feet without the roof, and weighing 10 tons, was carried 24 yards while falling 3 feet, (p. 1064.) The wind struck it nearly on the end.

13. An oak sill, 16 feet by 8¼ inches, and weighing 300 pounds, was driven 4 feet into

Digitized by Google

black loam at an angle of 45°. It was carried 25 yards northeast with the house, and 18 yards east after parting from the house, (p. 1064.)

14. A granary, exposing 128 square feet of surface, and weighing 60,000 pounds, was pushed 14 feet, (p. 1064.)

15. A plank 16 feet by 1 foot by 2 inches, was driven 4 feet into the soil at an angle of 45°, (p. 1064.)

16. A corn-sheller, weighing 640 pounds, was carried 400 yards, (p. 1064.)

17. An oak board, 4½ feet, 4 by 1 inches, was driven through an oak post 4 inches in diameter, (p. 1066.)

18. A house, exposing a surface of 392 square feet, + the slanting roof, and weighing 20 tons, was carried forward 18 feet while falling 2 feet, (p. 1066.)

19. A house, exposing 533 square feet, and weighing about 25 tons, was pushed from its foundations, (p. 1068.)

20. A beam 14 feet by 6 by 2½ inches was driven 3 feet into the soil in a slanting direction. Its weight was 50 pounds, (p. 1066.)

21. A stove, exposing a surface of 3 feet by 21 inches, was pushed 12 feet, (p. 1068.)

22. A granary, exposing a surface of 256 square feet to the wind, and weighing 55,000 pounds, was carried 21 yards while falling 6 feet, (p. 1068.)

23. A bell, exposing a surface of 1 square foot, weighing 115 pounds, and suspended 12 feet high, was carried 60 feet, (p. 1068.)

24. A hog weighing 200 pounds was carried 500 yards, (p. 1068.)

25. A green log of water-elm, 8 feet long by 7 feet in circumference, and weighing 2,000 pounds, was carried 50 yards, (p. 1069.)

26. A horse, weighing 1,080 pounds, was carried 45 yards, (p. 1069.)

It will be better to treat all similar examples together, and first let us examine the data concerning the houses.

If we estimate the static friction of a frame house upon a stone foundation or upon posts firmly fixed into the ground, and to which it is nailed, at one-half the weight of the house, it does not seem likely that we shall err by excess. Upon this basis it is easy to calculate the minimum velocity of a horizontal wind necessary to push it from its foundations. The difficulty is that we are dealing with a wind having a perpendicular component to its velocity. If the wall of the house was perfectly smooth, and since the air is nearly perfectly elastic, the only force exerted upon it by a wind blowing at any angle to its surface would be perpendicular to that surface. Moreover, whatever force the perpendicular component may exercise upon the wall, owing to its roughness, must have upon the house the effect of an overturning rather than a lifting power. But, since friction is independent of extent of surface, this overturning power would not assist in overcoming friction. The fact, also, that the houses, while being carried bodily through the air, were not made to spin round on an axis by this perpendicular component, there being then no resistance, beyond inertion, to motion in a circle, would seem to prove that its effect was not great. It would, therefore, appear that an approximation may be made to the velocity of the horizontal wind by simply calculating upon the given assumption of the relation of weight to friction the minimum force required to push these houses from their foundations. The following are the results for the given cases:

1. Pressure per square foot 41.7 pounds. Velocity of wind 91.3 miles per hour.
10. Pressure 71.4 pounds. Velocity 119.5 miles.
12. Pressure 56.8 pounds. Velocity 106.6 miles.
14. Pressure 234.3 pounds. Velocity 216.5 miles.
18. Pressure 51 pounds. Velocity 100.9 miles.
19. Pressure 46.9 pounds. Velocity 96.8 miles.
22. Pressure 107.4 pounds. Velocity 146.6 miles.

The roofs in these calculations have been neglected when the wind struck the side of the house, because if the wind was ascending at an angle of 45° it would not strike the roof at all, and even a much less angle of inclination would produce a comparatively small effect; for if the wind were blowing horizontally 70 per cent. of its total force would be exerted perpendicularly to the roof. This 70 per cent. would be resolved into two components of 70 per cent. each, or of 49 per cent. of the force of the wind, one of which would add to the weight of the house and consequently increase the friction by one-half its amount, while the other would aid in overcoming the friction. Thus, even in the case of a horizontal wind exerted upon a roof sloping at 45°, only 24½ per cent. of its total amount is effective to aid in overcoming friction; that is, neglecting the friction of the wind against the roof.

Only one of these buildings was not, in addition to being pushed from its foundation, carried away, viz, case 14. It, however, was pushed through a dense mass of tough rubbish, and its sides were bent from the perpendicular. Owing to its small surface and great weight the force of the wind exceeded the minimum required to push the building from its foundations less in this case than in any of the others. Hence we have the great velocity of 216.4 miles per hour, or of 317.4 feet per second, in a horizon-

age-machine, exposing a surface of 48 square inches, and weighing 15
arried away. The lifting power must have exceeded 45 pounds per
which corresponds to a perpendicular component of 94.8 miles.
e-power machine, exposing a surface of 2 square feet, and weighing 2,400
was pushed along the ground for 6 yards. The machine lay close upon the
., allowing very little scope for lifting power. The static friction could not
been less than one-fourth the weight. Allowing one-fourth the weight of the
chine for the lifting component of the wind, which is undoubtedly an exaggeration,
ere still remains a pressure of 225 pounds per square foot, horizontally, or a velocity
of two hundred and twelve miles per hour.

2. A beam, exposing a surface of 7 square feet, and weighing 25 pounds, was driven into the ground 3 feet 9 inches, at an angle of 35°. The area of the end of the beam was 8 square inches. A columbiad 10-inch shell, when filled, weighs about 100 pounds. At the distance of 100 yards such a shell penetrated compact earth 33 inches. Its velocity at the time of impact would be about 1,200 feet per second. The earth into which the beam was driven was black mold, which had never, beyond the depth of a few inches, been disturbed by the plow. It was wet at the time. If we estimate its resistance at half that of compact earth it is not likely we shall overrate it. The columbiad shell on these premises would have penetrated the mold 66 inches. The area of a great circle of the ball is 78.54 inches. The weight, therefore, for the square inch of resisting surface amounts to $100 - 78.54 = 1.27$ pounds. The weight of the beam per square inch of its end is $25 \div 8 = 3.1$ pounds. We have, therefore, the following equation:

$$\frac{1.27 \times 45 \times (1200)^2}{3.1 \times 66} = X^2$$

hen X is the velocity of the beam in feet per second, = 634 feet. This gives the beam velocity of 432.3 miles per hour, which is evidently erroneous, for it was accelerated this enormous velocity within a space of 35 yards. Gravity acting through this istance could only have produced a velocity of 82 feet. Since the force is as the square f the velocity, the following equation gives the force of the wind upon the beam:

$$\frac{(75)^2 \times 25}{(82)^2} = \text{force} = 2{,}233 \text{ pounds pressure.}$$

Since the surface upon which this force as exerted did not exceed 0.7 square foot, the above pressure has to be increased by ne-fourth its amount in order to obtain the pressure per square foot. The result is erefore evidently very erroneous.

Calculations from similar data give like stupendous results. Perhaps, however, e apparently prodigious velocities imparted to these flying timbers may point to the ct that at some elevation above the ground the velocity of the wind was vastly reater than at the surface. It may be also that the timbers were carried to a great evation, and thus owed a large part of their rapidity of motion to gravity. There also much uncertainty concerning the resistance of soils. I shall, therefore, leave e remaining data uncalculated, as involving too many unknown quantities.

tal direction. It is also probable that in this case the kinetic friction was greater than the static, and that it increased every moment until the building came to a stand.

In the case of the other houses the maximum velocity of the wind was by no means necessary to push them from their foundations. They were in addition shot forward as if from a cannon, without touching the ground while almost grazing it, and at the same time maintaining their normal position. We have the testimony of one eye-witness that the house went like the railroad; of another that it went like lightning. Since the house in the former case only traveled 40 yards, (p. 1063,) and in the latter only 75 yards, the above expressions would appear to justify the assumption that the acceleration of the houses could not have been less than that produced by gravity, or 32 feet per second. This would require a force double of that necessary to overcome friction on the assumed basis. This gives in case 12 a pressure of 113.6 pounds, or a velocity of 150.7 miles per hour.

There is yet another way of calculating the velocity of the wind from these houses. We have seen that in several cases they went forward in a well-nigh normal position close to the ground, and falling as they went.

The perpendicular component of the wind's force exerted upon the side of the building should, we have seen, if effective, tend to make the building revolve, and so throw it out of its normal position. Since this did not take place we assume that the force was not effective. If, therefore, we find by comparison of the force required to impart motion to a body sufficient to enable it to travel over the horizontal distances given, while the force of gravity is drawing it through the perpendicular spaces given, that is unreasonably great, we shall have good grounds for concluding that there was somehow a lifting power exerted other than that due to the perpendicular component of the force of the wind.

Let us examine case 12. The house falls 3 feet while traveling 24 yards. In the time during which it traveled, therefore, the motion of the house due to the force of the wind was 24 yards or 72 feet, while that due to the force of gravity amounted only to 3 feet; that is, the acceleration caused by the wind was 24 times greater than that caused by gravity. Now the force is as the square of the acceleration. Hence, if a lifting power had been exerted, the force of the wind must have been 576 times that of gravity. This gives a total pressure upon the side of the house of 5,760 tons, or 32.7 tons to the square foot, which is absurd, for the force generated by a difference of pressure cannot exceed that generated by a difference of a whole atmosphere, and that amounts only to about 3,350 pounds per square foot. We are, therefore, irresistibly drawn to the conclusion that the houses, while being driven forward, were partially supported by the wind. We may learn how this was accomplished by studying case 10. The house was first pushed from its foundation for 6 feet, then turned upon its edge, and afterward lifted over the tops of trees 20 feet high. Probably the trees were so near as to allow the house to ascend at an angle of 45°, thus reducing the height to be ascended to about 16 feet. The problem is how to apply a wind in order to generate the force required. We have the evidence of L. W. Low, (p. 1050,) that as soon as his house turned up on its edge, the flooring flew to the roof. This is probably the usual procedure in similar cases, and its cause is this: as soon as the edge of the house is lifted the wind rushes in, and finding its further progress barred, becomes instantly compressed by the wind in rear. It thus exerts over the whole interior of the house a pressure nearly equal to that exerted upon one side of it by the wind. If the house is a weak one the immediate result is that it is burst asunder. If it is a strong one, as it evidently was in this case, the compressed air, acting on the one side and the ground, and on the other side on the inside of the house will, if the compression be sufficiently great, lift the house. The area of the floor of the house in question was 480 square feet, and its weight was twenty tons. The pressure per square foot exerted perpendicularly to the area of the floor, required, in order to lift the house, was therefore 83.3 pounds. But the force actually exerted did not alone suffice to lift the building. It must have raised it in a very brief period to a height of 16 feet; for the action of the wind urging it forward was yet in full operation. If we suppose that it occupied one second in ascending these 16 feet, the lifting power exerted must have been double that of gravitation, or 166.7 pounds per square foot. Moreover, by the hypothesis, the force in these calculations has to be applied perpendicularly to the house. But actually it was not, the house being tilted up on its edge. Some of the power of the wind would also be lost by escaping through openings. Further, as soon as the house was lifted from the ground the resistance to the wind, and therefore the compression in the interior of the house, would be in a great measure removed. A pressure of 200 pounds per square foot would appear, therefore, inadequate to accomplish the work; that is, a pressure of the wind, or a velocity of two hundred miles per hour.

It is readily perceived that a body which is being accelerated by the wind while it partially presents its under surface to it, have the action of gravity upon it counteracted according to the extent of the surface exposed, &c. Such, I conceive, was the manner in which the houses, while traveling forward, were in the main partly relieved of the effects of gravity.

The extreme difficulty of obtaining even an approximation to the velocity of the wind is very appreciable in these calculations. In my opinion the best case is that of 14, because of its remaining firmly on the ground. The total weight of itself and contents was also easily obtained. I therefore conclude that since the wind in this case had a velocity exceeding two hundred and sixteen miles per hour, that it had a velocity equally great over a large portion of its path, and at particular points sometimes greater.

A horse or a cow of 1,000 pounds weight does not probably expose a greater surface to the wind than 12 square feet. Many cows and some horses of this weight were carried long distances. The lifting force of the wind, therefore, must in these cases have exceeded $1,000 \div 12 = 83.3$ pounds per square foot, and its velocity 129.8 miles per hour perpendicularly.

21. A stove weighing 450 pounds and exposing 7½ square feet of surface was pushed 12 feet. Estimating static friction at one-half the weight the pressure must have been 30.7 pounds per square foot, and the velocity 78.3 miles horizontally.

25. A log of water-elm, exposing a surface of 17.8 square feet and weighing 2,000 pounds, was carried 50 yards. It was probably barely lifted from the ground, if it was carried, because it did not strike deeply into the soil when it stopped. Its path could not be traced by marks left on the ground. The lifting power of the wind, in order just to balance gravity, must have been 112.3 pounds per square foot, representing a perpendicular velocity of 149.8 miles. It may be asked how a perpendicular wind was possible close to the ground. The answer in regard to the log is that the horizontal wind would become compressed between the bulge of the tree and the ground. In that case, however, the surface exposed is not so large. The whole bears ample evidence of a terrific but incalculable wind.

3. An iron sausage-machine, exposing a surface of 48 square inches, and weighing 15 pounds, was carried away. The lifting power must have exceeded 45 pounds per square foot, which corresponds to a perpendicular component of 94.8 miles.

6. A horse-power machine, exposing a surface of 2 square feet, and weighing 2,400 pounds, was pushed along the ground for 6 yards. The machine lay close upon the ground, allowing very little scope for lifting power. The static friction could not have been less than one-fourth the weight. Allowing one-fourth the weight of the machine for the lifting component of the wind, which is undoubtedly an exaggeration, there still remains a pressure of 225 pounds per square foot, horizontally, or a velocity of two hundred and twelve miles per hour.

2. A beam, exposing a surface of 7 square feet, and weighing 25 pounds, was driven into the ground 3 feet 9 inches, at an angle of 35°. The area of the end of the beam was 8 square inches. A columbiad 10-inch shell, when filled, weighs about 100 pounds. At the distance of 100 yards such a shell penetrated compact earth 33 inches. Its velocity at the time of impact would be about 1,200 feet per second. The earth into which the beam was driven was black mold, which had never, beyond the depth of a few inches, been disturbed by the plow. It was wet at the time. If we estimate its resistance at half that of compact earth it is not likely we shall overrate it. The columbiad shell in these premises would have penetrated the mold 66 inches. The area of a great circle of the ball is 78.54 inches. The weight, therefore, for the square inch of resisting surface amounts to $100 - 78.54 = 1.27$ pounds. The weight of the beam per square inch of its end is $25 \div 8 = 3.1$ pounds. We have, therefore, the following equation:

$$\frac{1.27 \times 45 \times (1200)^2}{3.1 \times 66} = X^2$$

when X is the velocity of the beam in feet per second, = 634 feet. This gives the beam a velocity of 432.3 miles per hour, which is evidently erroneous, for it was accelerated in this enormous velocity within a space of 35 yards. Gravity acting through this distance could only have produced a velocity of 82 feet. Since the force is as the square of the velocity, the following equation gives the force of the wind upon the beam:

$$\frac{(75)^2 \times 25}{(82)^2} = \text{force} = 2{,}233 \text{ pounds pressure.}$$

Since the surface upon which this force was exerted did not exceed 0.7 square foot, the above pressure has to be increased by one-fourth its amount in order to obtain the pressure per square foot. The result is therefore evidently very erroneous.

Calculations from similar data give like stupendous results. Perhaps, however, the apparently prodigious velocities imparted to these flying timbers may point to the fact that at some elevation above the ground the velocity of the wind was vastly greater than at the surface. It may be also that the timbers were carried to a great elevation, and thus owed a large part of their rapidity of motion to gravity. There is also much uncertainty concerning the resistance of soils. I shall, therefore, leave the remaining data uncalculated, as involving too many unknown quantities.

The amount of the precipitation.

It was impossible to obtain more than generalities on this head. There were no rain-gauge measurements so far as I could learn. At Davenport, however, a few miles from where damage was done on the Mississippi, there fell, on May 22, 1.35 inches, as shown by the signal-service reports. From the description of the rain to the north of the tunnel, in Washington County, a greater quantity than this must have fallen at many places. It is not, therefore, likely that we shall overestimate the amount when we assume that two inches of rain fell over an area ten miles in width. Since the tornado traveled thirty miles per hour, this gives a rain-fall per minute of $\frac{2\times(10\times\frac{1}{2})\times3097600\times9\times14}{1728}$ = 23,232,000 cubic feet.

Tornado dynamics.

A cubic foot of water weighs 1,000 ounces. The weight of water which fell per minute was, therefore, $\frac{23232000\times1000}{16}$ = 1,452,000,000 pounds. It is not, probably, an exaggeration to assume that this mass of water fell on an average 6 miles or more. This gives a horse-power of $\frac{1452000000\times(6\times5289)}{33000}$ = 1,393,920,000 generated by the falling water.

From the calculations of the velocity of the wind, it is not probable that, when we assume, at the distance of 100 yards from the center, an average velocity of 12 miles per hour, we overrate it. The angle (p. 1088) which the wind made with the tangent was probably about 25°. The wind, therefore, on these bases, enters a cylinder of 100 yards radius at the rate of 50 miles per hour or 4,400 feet per minute.

From the calculations of the height of the centripetal current, we have seen that it probably extended over two miles. Let us assume that its height was two miles. Let us assume also that the velocity with which the wind entered the cylinder was equally great throughout its length. We have then the following data for calculating the quantity of air which enters this cylinder of 100 yards radius, or 628.318 yards circumference per minute. It amounts to (628.318×3) × 4,400 × (2×1,760×3) cubic feet = 87,582,502,656,000 cubic feet. Since this volume is calculated from the mechanical effects or force of the wind, and since the relation between the force and the velocity of the wind is calculated for the average pressure, it matters not in calculating the weight of the above volume of air what the barometric pressure was at the distance of 100 yards from the center. The difference of pressure due to elevation must, however, be calculated. Since the average pressure at sea-level is about thirty inches, at an elevation of one mile about 24.60 inches, and an elevation of two miles about 20 inches, and taking into account the correction due to the elevation of the country over which the tornado passed, 24 inches would be about the mean pressure up to two miles of elevation. The density of the air varies with the temperature. From the data given on page 1093, the temperature around the tornado must have been, at a fair exposure, about 76°, but was in deep-wooded ravines no doubt much greater. Since the temperature diminishes 1° for every 300 or 400 feet elevation, we may assume the average temperature to have been within the lower part of the centripetal current about 60°. The relative humidity (p. 1072) was about 65 per cent.

The weight of a cubic foot of air, at a pressure of 24 inches, a temperature of 60° and a relative humidity of 65 per cent., is 426 grs., or thereabout. The total weight of air, therefore, entering the column per minute amounts to $\frac{875825026560000\times426}{7000}$ = 53,302,020,875,922 pounds. This weight of air moves by hypothesis at the rate of one hundred and twenty miles per hour, or of 170 feet per second. This velocity is acquired from the acceleration due to gravity in falling through a space of 481 feet. The power therefore, generated by this mass of air moving with the given velocity amounts to $\frac{53302020875922\times481}{33000}$ = 77,689,092,161,166 horse-power.

The latent heat of evaporation amounts to about 1,000°. Consequently the condensation of 1,452,000,000 pounds of vapor is accompanied by the evolution of 1,452,000,000 × 1,000 calories or pound-degrees of heat. The specific thermal capacity of air, as compared with water, is as .237 to 1. The number of degrees through which this amount of heat would raise 1 pound of air, is 1,452,000,000,000 ÷ .237 = 6,126,582,278,481 degrees. But the pressure remaining the same, air expands $\frac{1}{491}$ of its volume for every accretion of 1 degree of temperature. This amount of heat would, therefore, expand 1 pound of air, 6,126,582,278,481 ÷ 491 = 12,477,764,319 cubic feet. A cubic foot of air at 30 inches pressure, 60° temperature, and having a relative humidity of 65 per cent., weighs 538.6 grains. A pound of such air, therefore, occupies 7,000 ÷ 538.6 = 12.99 cubic feet = or very nearly 13 cubic feet. A pound of air, therefore, in doubling its volume must, the pressure remaining 15 pounds per square inch, [illegible]

Digitized by Google

weight of $13 \times 144 \times 15 = 28{,}080$ pounds through 1 foot. The total amount of work, therefore, performed by one pound of air, while expanding under a pressure of 15 pounds per square inch to 12,477,764,315 times its original bulk, is $12{,}477{,}764{,}315 \times 28{,}080$ foot-pounds. This amount of work accomplished per minute demands $\frac{12477764315 \times 28080}{33000} = 10{,}617{,}443{,}089.8$ horse-power.

We thus see that the power generated by the condensation of the amount of vapor estimated as having been precipitated is much less than that calculated to have been produced by the velocity of the centripetal winds. Theoretically this power should be diminished by the amount of expansion counteracted by the removal of so large a mass of vapor. Practically, however, it seems probable that this removal of vapor, while increasing the specific gravity of the air, yet when taking place with great rapidity serves rather to increase the rarefaction.

The horse-power required to raise 5,330,020,875,922 pounds to a height of five miles per minute amounts to $\frac{5330020875922 \times 5 \times 1760 \times 3}{33000} = 4{,}264{,}016{,}700{,}737.6$ horse-power.

These figures convey a better idea of the tremendous power of the tornado than any mere verbal description could do. They also show that the power evolved by the condensation of vapor, while enormous, is by no means sufficient to supply the whole energy developed by the tornado. We must therefore look for another source of power. This is no doubt to be found in the destruction of the atmospheric equilibrium by an abnormally-warm southerly current flowing under a much colder and consequently specifically heavier stratum of air. This brings us to the consideration of the general atmospheric conditions under which the tornado originated.

General atmospheric conditions.

An area of low barometer existed in the Mississippi and Missouri Valleys on the 20th, 21st, and 22d of May, which moved very slowly northward. This induced a southerly current, abnormally warm for the season, over a large portion of the interior of the continent. The result was a series of violent local storms, or spasmodic atmospheric convulsions, along the whole southern declivity of low barometer. These storms were generally accompanied by hail, and always by lightning. They reached a climax in the tornado, which is the subject of this paper, and in that which simultaneously devastated a portion of Kansas. The circumstances under which these terrible meteors arise are, therefore, easy of comprehension. They are the same as those which produce the beneficent thunder-shower, only they exist in greater intensity. The warm southern current, drawn toward the center of low barometer, passes under much colder and heavier air. So long as the greater specific gravity of a given volume of the upper stratum of air, which is due to a lower temperature, is balanced in the lower stratum by the greater density, consequent upon greater pressure of the same volume of air, so long may the atmosphere remain in a state of unstable equilibrum. Any disturbing cause may, however, destroy this state of unstable equilibrum, because the moment the pressure upon the underlying warm air becomes equal to that upon the upper stratum, it becomes the less dense, and, therefore, specifically lighter. Consequently, as soon as an opening is broken through the upper strata, the state of unstable equilibrum is immediately destroyed, and a powerful ascending current formed. It is manifest that the state of unstable equilibrium may continue until the density arising from the lower temperature exceeds that arising from the greater pressure. The moment this occurs, the unstable equilibrium is destroyed. The nearer the atmosphere approaches to this condition, the more intense will be the consequent convulsion. It seems probable that in the case of tornadoes this total destruction of equilibrium is a frequent, if not a constant, accompaniment.

The electrical phenomena.

On this subject there is a general harmony among the witnesses. In the lofty centrifugal cloud there was incessant thunder and lightning; but very little, if any at all, in the centripetal cloud and the funnel. One object, a tree, was struck in the path of the storm; but the discharge took place a half hour before the arrival of the funnel. The lightning-rod said to have been melted on Widow Dogget's barn might have been struck long before, and only noticed then because it was blown down.

There was no evidence of electrical action upon the trees, which were peeled and shivered by the storm, although there was that broom appearance where the trees were broken, which has been referred to the action of electricity. This, however, was clearly due to the straining of the tree before it broke.

No one saw any objects tipped with electrical light during the progress of the storm. The telegraph was not interrupted until the wind blew down the wires.

The electrical phenomena must, therefore, be regarded as merely secondary, as the result of the very rapid condensation of the vapor of water due to atmospheric disturbances arising from other causes.

Explosion from rarefaction.

It is the generally accepted opinion that in tornadoes houses are frequently burst asunder when the center of the whirlwind comes over them. This is supposed to be accomplished by the great rarefaction, which is said to exist in the center, suddenly relieving the air within the houses of a large portion of atmospheric pressure. The air thus relieved of pressure immediately expands and blows the house asunder as with gunpowder. There was not, so far as I was able to learn, a single case in which a house was so destroyed. The houses were invariably demolished or blown from their foundations by a wind blowing in a certain direction. They were generally pushed or carried a considerable distance bodily, floor and all. After striking the ground with the foremost edge they turn partially over, thus exposing the floor to the wind. The wind being obstructed by the wall of the house resting on the ground became immediately compressed by the pressure from behind. The floor, unable to stand this pressure, went upward, and the whole interior of the building became subjected to a strong pressure due to the compression of the air. This pressure was more than balanced on the side struck by the wind. On the other sides there was nothing to resist it, and the house was accordingly burst asunder. Some of the houses, which were carried forward, evidently reached the center before striking the ground. Traveling with rapidity, they would cross the narrow interval of calm in the eye of the tornado, if such there be, in a small fraction of a second. Being then struck by a contrary wind they were shattered into fragments and dispersed. Such may have been the case with the houses of M. Davidson and Peter Marsh.

Some houses went to pieces the moment the doors and windows were blown in. This takes place by the same kind of explosion as that mentioned above, and which is due to the law that fluids press equally in all directions. If a window is blown in on the windward side of the house, and there is no outlet for the inrushing wind, the whole interior of the house is immediately subjected to a force equal, or nearly so, to that of the wind. Explosion accordingly takes place. In a case of explosion of this kind the floor of the house generally remained, and once at least the windward side of the house had merely fallen forward, when the other sides had left it. We have, therefore, ample proof of explosion by compression, but none whatever of explosion by rarefaction. When the tornado was raging with full fury no house could possibly stand on its foundations until the center came over it. If the tornado was not strong enough to blow down a house before it reached the center, the house remained standing, or was demolished by the winds in the rear of the storm-center.

The belief that at the center of the tornado there exists a rarefaction almost amounting to a vacuum, is the product of the formerly widely entertained theory that tornadoes are mere whirls of wind, generated by some such mechanical agency as the meeting of two opposing currents. According to this theory the low barometric pressure towards the center is the result of the centrifugal force generated by the whirl throwing the air away from the center. Now, that we know that the whirling motion is merely a result impressed upon the winds rushing toward the center of low pressure by secondary causes, our views respecting the amount of rarefaction in the eye of the tornado must undergo a change. Without doubt, the pressure there reaches its minimum, because thither the winds tend. That the progress of the inrushing winds is delayed by centrifugal force is certain, and as soon as the centrifugal force becomes equal to the centripetal the wind will cease to be accelerated toward the center. At that point they will ascend circling, and losing part of their circular motion by friction will be drawn nearer the center until it becomes the focus of most rapidly ascending winds.

The fact that there were no evidences of the bark of trees having been torn off by the sudden evaporation of the juices of the trees, due to the relief from pressure, has already in the statement of facts been sufficiently insisted upon.

The temperature at the center.

A great many witnesses felt somewhat cold as the storm passed over them. The temperature is easily calculated. We have assumed, from the data, an average temperature of 76° on the surface of the ground, and a relative humidity of 65 per cent. This gives a dew-point of 63° or thereabout. This sudden decrease of 13°, together with the wet, is sufficient to account for the coolness experienced.

The amount of rarefaction necessary to produce this diminution of temperature.

The lowering of the temperature at the center of the tornado is due to the work performed by the air in expanding under diminishing pressure. The amount of this expansion, and consequently of the diminution of pressure, is easily obtained from the equation $\frac{a+t}{a+t_1} = \left(\frac{v_1}{v}\right)^{\kappa-1}$, (Zeuner's Grundzüge, p. 131,) where a = co-efficient of expansion = 491, t = initial temperature − 32, t_1 = final temperature − 32, v = initial

Digitized by Google

volume, r_1 = final volume, and x = the relation between the thermal capacities of the air with constant volume and with constant pressure = 1.41. The initial temperature in the case of the tornado = 76°, and the final temperature 63°. Consequently, $t = 76 - 32 = 44$, and $t_1 = 63 - 32 = 31$. Let us take $r = 1$. Then $\frac{491+44}{491+31} = \left(\frac{r_1}{1}\right)^{1.41-1}$, or $\frac{535}{522} = r_1^{.41}$, $r_1 = \left(\frac{535}{522}\right)^{\frac{1}{.41}} = 1.8219$. A cubic foot of air, therefore, expands in passing from the circumference to the center to 1.8219 cubic feet. But the pressure is inversely as the volume. Therefore, since the initial pressure was 28.5, $\frac{1 \times 28.5}{1.8219}$ = the pressure when the dew-point is reached and the funnel commences, = 15.69 inches. This gives a diminution of 12.81 inches, corresponding to a pressure of about 6.40 pounds per square inch, or 922 pounds per square foot, an amount of potential energy more than sufficient to account for all the phenomena.

The form and dimensions of the visible funnel did not, therefore, depend upon the diminution of pressure alone, but also upon the temperature and relative humidity of the inrushing winds. Its presence accordingly does not indicate a certain invariable velocity of the wind. When the air is moist, as it always is over the sea, a very small diminution of pressure, and consequently a comparatively light wind, would suffice to develop the phenomenon of a visible funnel. When, on the contrary, the air is very dry, winds of the utmost possible violence could be produced without a visible funnel. The funnel of dark cloud, therefore, by no means indicates the limits of the ascending current. This renders the explanation of the hovering up and down of the lower end of the funnel easy of comprehension. Varying humidity along the path of the tornado would be sufficient to produce this phenomenon.

As the air ascends the pressure diminishes, and the funnel consequently increases in width. The diminution of pressure perpendicularly is symmetrical, and the result is the symmetry of the form of the funnel.

Did the tornado carry up water? Beyond a doubt; but just as it carried up any other body. Water, readily separating into small portions under the action of the wind, would be much more likely to reach the summit of the cloud than particles of solid matter, however fine. It is a common belief, not merely among the many but among men of science, that evaporation takes place rapidly within the vortex of the tornado or water-spout. The fact that the dark funnel is merely a cloud formed by the condensation of the vapor of air, the temperature of which has fallen below the dew-point, is sufficient to show the impossibility of this. Water, therefore, does not add to the power of the tornado. It passes up as a liquid and comes down as a liquid or solid. Even if it were evaporated by the tornado it would require precisely the same amount of heat to evaporate it as it would give forth upon being again condensed.

The sound.

Its loudness was extreme, yet of such a nature as to drown all other sounds without stunning. A man could stand by his house, as it was shivered to pieces, and not hear the noise of its breaking. Many likened it to heavy railroad-trains. To a few it appeared like the hum and whir of innumerable machinery. To others it resembled the roaring of the ocean, along a rocky shore, in a storm. To the soldier it recalled the rolling thunder of the battle-field. Those who were nearest to it were not aware of its terrific loudness.

B. Whitaker heard it, together with others, at the distance of sixty miles. He says that even at that distance it indicated great force. Doubtless it was heard much farther, but excited no attention, being attributed to some other cause. The barometric gradient inclined from Mr. Whitaker to the tornado, consequently the propagation of the sound received no help from the wind. Thunder has very seldom been heard at a greater distance than ten miles. The sound of the tornado was therefore six times louder than the loudest thunder. Heavy cannonading has been heard, it is said, at the distance of ninety miles, and "the report of a volcano at St. Vincent was heard at Demerara, three hundred miles off." The voice of the tornado is, therefore, one of the strongest known to art or nature.

The distances to which bodies were carried.

Leaves fell at Keota and Prairie City which must have been carried four miles. Shutters were carried three miles. A tire of a wagon-wheel was carried two miles. A pig was carried one and one-fourth miles. Doubtless many heavy bodies were carried much farther than any of these instances. Wagons and pigs, &c., disappeared, and the owners could find no trace of them. Only the ruins which were carried the shortest distance were recognized. There is no evidence, however, of anything heavier than

Digitized by Google

leaves and mud having traveled farther than a mile from the vortex. They were carried along with it, it may be, for ten miles. This proves that these bodies either never reached so high as the centrifugal cloud, or, if they did so, were carried again into the vortex before reaching the ground. Hail fell at Sigourney, four miles from the center, containing fragments of grass and leaves, and particles of mud. These, therefore, were carried up into the centrifugal cloud, and were probably scattered over the whole region visited by the rain and hail storm.

Why the hail generally preceded the rain.

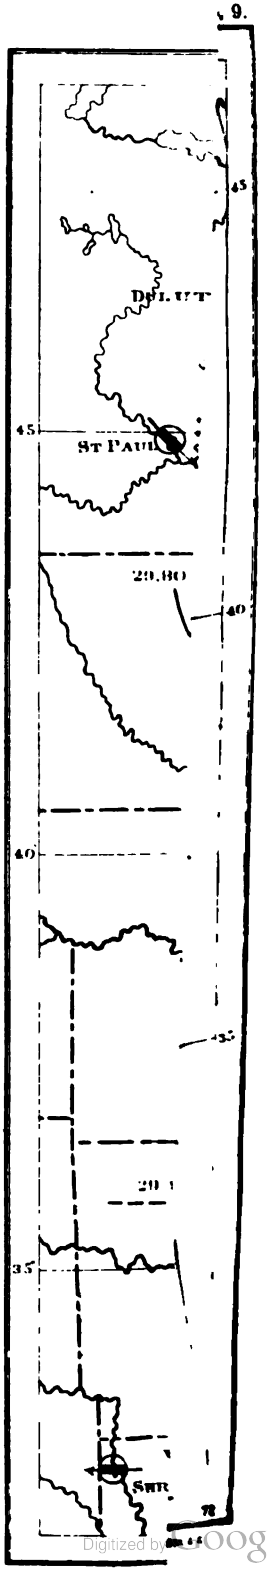
A drop of rain of the largest dimensions, falling through air of an average pressure cannot exceed a velocity of 34 feet per second. A hail, however, weighing ½ pound and measuring 4 inches in diameter can acquire a much greater velocity. The area of a circle 4 inches in diameter is 12.566 inches, or say 12½ inches. Before the motion of the hail ceases to be accelerated the air must oppose it with a resistance equal to its weight. A spherical surface experiences theoretically in its passage through the air only half that opposed to a plain surface. The roughness of the hail would considerably increase the retardation; but this would probably be more than counterbalanced by the fact that all of the hail were, more or less, flattened and cake-shaped, thus allowing the hail to assume in falling a position of least resistance. Hence, the air must oppose the hail with a pressure of $\frac{144}{12\frac{1}{2}} = 11.5$ pounds per square foot before its motion ceases to be accelerated. This corresponds to a velocity of forty-eight miles per hour, or 70.4 feet per second. Since the resistance of the air is directly as the density, the velocity possible to be attained would be doubled at the height of three or four miles. We thus perceive that the hail, although perhaps formed at a greater elevation than the rain, can yet, when large, reach the ground before it.

The enormous height from which the hail fell, and the vast thickness of the cloud, does away with the difficulty which many have experienced of conceiving how hail can be sustained a sufficient length of time in the air to allow it to grow to such large proportions.

The light which the tornado throws upon the higher currents of the atmosphere is valuable. At a height of from ten to fifteen miles, there was in Iowa a rapid current to the northeast.

The predominance of winds blowing parallel to the path of the tornado.

The width of the destruction on the right of the center of the storm-path was, we have seen, always greater than that on the left. Another fact of the same significance is that the tornado, when it first commences its destructive career, and when the black funnel hovers over the surface of the ground without touching it, manifests itself as a wind blowing in the line of the storm. The reason is evident. The winds blowing in spirals toward the center had, in addition to a motion along the spirals, a motion as constituent parts of the storm in the direction of its path and at the rate of thirty miles per hour. This increased the velocity of the winds on the right of the center, and diminished that of those on the left of it. The general barometric gradient being inclined from south to north, tended also to increase the velocity of the southerly winds and diminish that of the northerly.



The tornado in Illinois.

The general appearance of the tornado, as a whole, in Illinois, was somewhat different from that which it presented in Iowa. The ascending column of air was no longer on one side of the centrifugal cloud, but apparently near its center. Hence the witnesses generally describe the cloud, as it approached, as consisting of a dark cloud to the northwest, a less dark to the southwest, and a clearer space between. Mr. Roe saw what he conceived to be three streaks of rain, when the tornado was yet miles from him, with clearer spaces between them. My own conception is that the rain fell so densely on both sides of the whirl as to be perfectly black, and the clearer portion, through which some of the witnesses saw the sky, was directly under the whirling cloud, and before the funnel reached to the earth. Mr. Roe, I believe, saw the two descending sheets of rain and the funnel, now reaching to the earth, extending down between them, with clearer intervals on either side. The fact that the cloud now extended on both sides of the funnel, and that the sun was bending toward the western horizon, from which the storm was approaching, rendered accurate observation very difficult. Hence comparatively few persons saw the funnel distinctly. Hence the disagreement of the witnesses as to the direction of revolution. In Iowa all circumstances had combined in order to render precise observation easy. In Illinois the very reverse was the case. I shall, therefore, treat this portion of the subject in a few general remarks.

ɔrnado developed energy in this State quite as great as that displayed in Iowa. tion of revolution was the same. The disposition of the ruins was precisely It showed the same, and even a greater, partiality for water-courses, turning from its course in order to follow them. Its direction varied between north- southeast, and was in the main easterly. At the moment when its velocity ed, and before reaching Spoon River, it poured down, close to the whirlwind, on its very path, a perfect cataract of water. The height of the cloud must ɔn very great, for it was seen in the west for hours previous to its advent. ıs less hail, and the sound was not so generally noticed as in Iowa.

The identity of the tornado in Iowa with that in Illinois.

ost track of, the Iowa tornado was close upon the Iowa River, and traveling theast. Its general course had, however, been easterly. A very severe rain- sed over the district between its point of disappearance and the Mississippi rains were delayed by it and bridges washed away. On the Mississippi itself age was done to shipping by a violent gust of wind, which accompanied the Monmouth there was a severe thunder-storm. Twenty miles to the south of ado again struck the ground. It was at Youngstown at 5.45 p. m., or thereby. IcKee's house, north of Washington, Iowa, to Youngstown, is a distance of y-three miles in a straight line. The tornado was at McKee's house at 3.10 e difference between 5.45 and 3.10 is 2.35. The discrepancy due to is four minutes, very nearly. The time, therefore, consumed by the storm g from opposite Washington, Iowa, to Youngstown, Ill., was 2 hours 31 r $2\frac{1}{2}$ hours; $63 \div 2\frac{1}{2} = 25\frac{1}{2}$, which is, therefore, the velocity of the storm, in ıour, in a straight line. The length of the journey was materially increased ıkedness of the path. This brings the velocity nearly up to that with which traversed Keokuk and Washington Counties, Iowa. These facts, taken in , irresistibly lead me to the conclusion that the tornadoes in the two States l the same.

t where the tornado first struck the ground, on South Skunk River, is situ- 20′ west longitude and 41° 15′ north latitude. It was finally lost track of , in 89° 37′ west longitude and 40° 40′ north latitude. The whole motion ado, therefore, was 2° 43′ east and 35′ south, or one hundred and forty- east and forty-one miles south. The mean direction of its path was 24° d 65° 9′ east, and its whole motion one hundred and forty-nine miles. The of its path renders its actual motion considerably greater.

ɛst thanks are due to Elias Colbert, of the Chicago Tribune, and the editors newspapers at Washington and Sigourney, Iowa, for assistance rendered, lly for publishing an extensive list of questions concerning the tornado, ɛd for me valuable information from persons residing at a distance.

Observer, Signal-Service, U. S. A.

PAPER 31.

THE STORM OF APRIL 14-18, 1873.

(With 9 maps.)

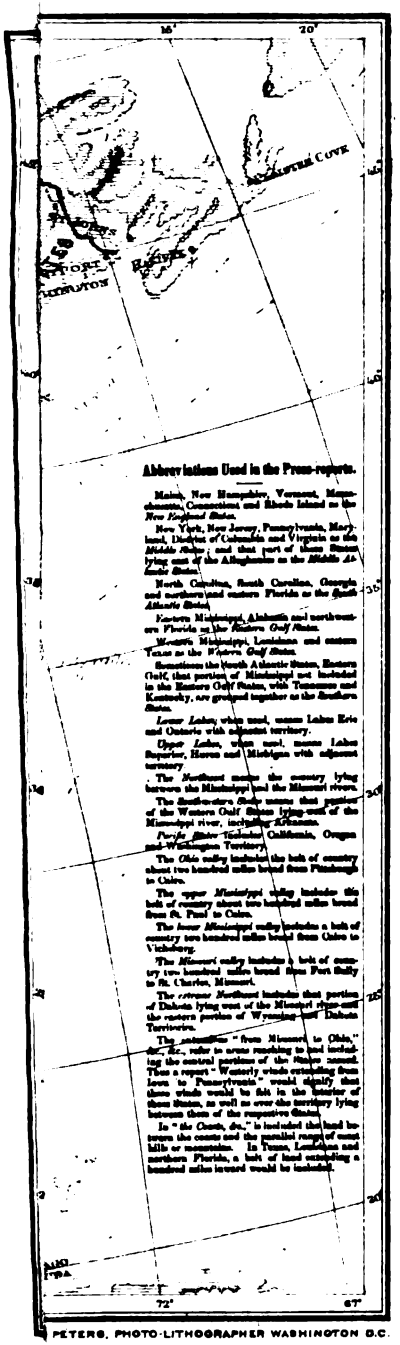
ıter that was found to exist in Dakota on the morning of April 13, con- ping itself slowly over Nebraska and Kansas during the afternoon and reatening weather and southeasterly winds in the Upper Mississippi and ys. Breckenridge, Minn., reported heavy snow the following morning, with y winds. The storm now commenced moving eastward toward the lakes, ıary signals, ordered up on the previous day, heralded its advent. a on the afternoon of April 14, it appeared to be moving remarkably slow, ısure was diminishing very rapidly eastward to Lake Erie. After reach- ıe midnight reports of April 15 showed that the storm-center had divided ımber of small but very distinct areas of barometric depressions, extend- to the Alleghanies, with threatening and rainy weather in the Ohio several small storm-centers united again during the following day, ption of one, which moved southeastwardly into the Carolinas. The enter now changed its easterly course to a northeasterly direction, l the lower lakes, but making very little progress; so much so, that the l almost stationary in Southern Michigan for sixteen consecutive hours.

Digitized by Google

The small area that had moved into the Carolinas also changed its direction, and appeared as a well-developed storm on the coast of New Jersey on the afternoon of Apr. 17. That area of low barometer which was over Illinois, Southern Michigan, and the Ohio Valley on the 16th, continued over nearly the same portion of country, with special storm-centers in Indiana and Lake Huron, up to the night of the 17th, when it moved northeastwardly to Lake Ontario by the morning of the 18th, where it prevailed as a very large area of low pressure over the entire lake region on the afternoon of the 18th. The midnight reports of this date, however, showed the storm to be confined to the Saint Lawrence Valley, with rain and snow and brisk westerly winds over the lakes. Moving along the Saint Lawrence, it again united over New Brunswick with that portion which had been moving along the Atlantic coast, and then disappeared beyond the limits of our stations. During the six days that this storm had been central in the United States, its frequent changes of direction, its dividing and reuniting have made it, in many respects, one of the most remarkable storms traced by the signal service since its organization. Lake-navigation being still closed, no disasters occurred to shipping, yet its severity was felt in most lake ports, which had, however, been duly warned of its approach.

PAPER 32.

CHRONOLOGICAL LIST OF AURORAS OBSERVED AT THE RESPECTIVE SIGNAL-SERVICE STATIONS FROM NOVEMBER 11, 1870, TO JULY 31, 1873, INCLUSIVE.



NOTE.—The dates are those of the evening of the night of the aurora, or of the nearest 11 p. m. observation, or according to astronomical reckoning.

† placed *before* the name of a station indicates that the observed light may possibly not have been an aurora.

† placed *after* the name of a station indicates that the date is doubtful, and may be 1 day in error.

Abbreviations Used in the Press-reports.

Maine, New Hampshire, Vermont, Massachusetts, Connecticut and Rhode Island as the *New England States.*

New York, New Jersey, Pennsylvania, Maryland, District of Columbia and Virginia as the *Middle States*; and that part of these States lying east of the Alleghanies as the *Middle Atlantic States.*

North Carolina, South Carolina, Georgia and northern and eastern Florida as the *South Atlantic States.*

Western Mississippi, Alabama and northwestern Florida as the *Eastern Gulf States.*

Eastern Mississippi, Louisiana and eastern Texas as the *Western Gulf States.*

Sometimes the South Atlantic States, Eastern Gulf, that portion of Mississippi not included in the Eastern Gulf States, with Tennessee and Kentucky, are grouped together as the *Southern States.*

Lower Lakes, when used, means Lakes Erie and Ontario with adjacent territory.

Upper Lakes, when used, means Lakes Superior, Huron and Michigan with adjacent territory.

The *Northwest* means the country lying between the Mississippi and the Missouri rivers.

The *Southwestern States* means that portion of the Western Gulf States lying east of the Mississippi river, including Arkansas.

Pacific States Included California, Oregon and Washington Territory.

The *Ohio valley* includes the belt of country about two hundred miles broad from Pittsburgh to Cairo.

The *upper Mississippi* valley includes the belt of country about two hundred miles broad from St. Paul to Cairo.

The *lower Mississippi* valley includes a belt of country two hundred miles broad from Cairo to Vicksburg.

The *Missouri* valley includes a belt of country two hundred miles broad from Fort Sully to St. Charles, Missouri.

The *extreme Northwest* includes that portion of Dakota lying west of the Missouri river and the western portion of Wyoming and Dakota Territories.

The expressions "from Missouri to Ohio," &c., &c., refer to areas reaching to and including the central portions of the States named. Thus a report "Westerly winds extending from Iowa to Pennsylvania" would signify that these winds would be felt in the interior of these States, as well as over the territory lying between them of the respective States.

In "the Ozarks, &c." is included the land between the coasts and the parallel range of coast hills or mountains. In Texas, Louisiana and northern Florida, a belt of land extending a hundred miles inward would be included.

PETERS, PHOTO-LITHOGRAPHER WASHINGTON D.C.

PAPER 33.

A.

LEGATION OF AUSTRIA-HUNGARY,
Washington, May 6, 1873.

MR. SECRETARY OF STATE: At the meeting of meteorologists at Leipsic, a series of questions were propounded for the purpose of bringing about greater uniformity in the meteorological labors of various countries, and greater unanimity in the development of this science, the influence of which upon the interests of navigation and agriculture is indisputable.

As a means of attaining this end, it is proposed to convene a congress of meteorologists, similar to the international assemblies which have met from time to time for the purpose of discussing scientific questions of international interest. It has been agreed that the congress shall commence its session next autumn, at the city of Vienna; and

Digitized by Google

that a committee shall be appointed to take charge of the preparatory labors, a committee to be composed of the following gentlemen: Dr. H. Wild, Dr. C. Bruhns, Dr. C. Jelinek.

In the fulfillment of this mission, Director Jelinek, on behalf of the committee just addressed a series of proposals to the imperial and royal minister of public instruction, asking at the same time, with a view to giving an official character to the projected congress, that these governments, which have hitherto favored the development of meteorological science, may be invited to send delegates, selected from among the heads of their meteorological institutes and the directors of observations having no connection with the State.

In consequence of this request, I have just received instructions from my government, Mr. Secretary of State, to send you ten copies of the report of the discussions which took place at the meeting of the meteorologists at Leipsic, and to invite, in its name, the Government of the United States to be pleased to take part in the projected congress, which will meet on the 1st of September, at Vienna, and which will remain in session for not more than fifteen days.

The encouragement which the Government of the United States has always given to the science in question, and the wonderful results which have been obtained by meteorological observations on this continent, renders its participation in the above-named congress in the highest degree desirable. I therefore entertain the hope that the Government of the United States will be pleased, in the interest of science and the general welfare, to join, by its representations at this congress, the experience of its meteorological institutes to the observations of the meteorologists of Europe, and thus the sphere of knowledge which is useful to mankind may be extended.

Be pleased to accept, Mr. Secretary of State, the assurance of my very high consideration.

LEDERER.

Hon. HAMILTON FISH,
Secretary of State, Washington.

B.

WAR DEPARTMENT,
Washington City, August 15, 1873.

SIR: Information having been communicated to this Department by the Department of State, that an invitation has been given by the Austrian government to the United States Government to take part in a congress of meterologists, to convene at Vienna on the 1st of September next, and the designation of a delegate to attend that congress having been committed to this Department, you are authorized to proceed to Vienna to represent the United States Government in the proposed congress.

You will inform the congress of the deep interest with which this Department regards whatever may relate to the advancement of systems of storm-warnings; and its desire that an interchange of international telegraphic weather-reports may be extended as widely as possible.

Very respectfully, your obedient servant,

WM. W. BELKNAP,
Secretary of War.

Gen. ALBERT J. MYER,
Chief Signal-Officer, U. S. A.

C.

MEMORANDUM.

The exchange of simultaneous reports between Russia and the United States to commence with those to be taken on January 1, 1874. The hour of observation 7.35 a. m., Washington (local) time. The reports will be exchanged by mail, the packages to be mailed on the 15th and last days of each month. The reports to be nearly as possible uniform in character and to exhibit at least pressure, temperature, wind, rain, relative humidity, and clouds.

F. C. WIL...

VIENNA, *September* 16.

MEMORANDUM.

The exchange of simultaneous reports between Turkey and the United States will commence with those to be taken on January 1, 1874. The hour of observation to be 7.35 a. m., Washington (local) time. The reports will be exchanged by mail. The packages to be mailed on the 15th and last days of each month. The reports to be as nearly as possible uniform in character and to exhibit at least pressure, temperature, wind, rain, relative humidity, and clouds.

COUMBARY,
Directeur de l'Observatoire impérial météorologique de Constantinople.

VIENNA, *September* 16, 1873.

PAPER 34.

The following table shows the percentage of verifications of probabilities for each division or subdivision named for each month, the monthly percentage of all, the yearly percentage of each, and the percentage of total verification.

Month.	New England.	Middle States.	South Atlantic.	Lower Lakes.	Eastern Gulf.	Ohio Valley.	Western Gulf.	Upper Lakes.	Northwest.	Monthly percentage for all sections.
1872.										
October	.79	.81	.79	.80	.77	.76	.77	.76	.76	.7788
November	.79	.79	.76	.76	.74	.80	.70	.74	.67	.7500
December	.91	.83	.79	.78	.80	.78	.76	.75	.73	.7812
1873.										
January	.82	.83	.79	.74	.75	.76	.76	.76	.72	.7700
February	.79	.80	.76	.80	.75	.70	.72	.76	.78	.7622+
March	.82	.79	.80	.78	.75	.77	.70	.74	.69	.7600
April	.82	.80	.84	.79	.77	.76	.78	.74	.77	.7850
May	.79	.79	.79	.75	.77	.74	.72	.73	.77	.7611
June	.81	.84	.87	.80	.74	.70	.....	.75	.72	.7787+
July	.87	.82	.83	.83	.80	.84	.79	.78	.76	.8133+
August	.84	.79	.80	.74	.77	.76	.74	.75	.74	.7700
September	.83	.85	.84	.79	.85	.80	.....	.77	.77	.8120
Yearly percentage for each section	.8150	.8117+	.7992	.7800	.7716+	.7642	.7440	.7525	.7400	9.3233+ ÷12 = .7769+
